Abstract

The task to assess the performance of quantum chemical methods in describing electronically excited states has in recent years started to shift from calculation of vertical (ΔE_{ve}) to calculation of 0–0 excitation energies (ΔE_{00}). Here, based on a set of 66 excited states of organic molecules for which high-resolution experimental ΔE_{00} energies are available and for which the approximate coupled-cluster singles and doubles (CC2) method performs particularly well, we explore the possibility to simplify the calculation of CC2-quality ΔE_{00} energies using composite procedures that partly replace CC2 with more economical methods. Specifically, we consider procedures that employ CC2 only for the ΔE_{ve} part and density functional theory methods for the cumbersome excited-state geometry optimizations and frequency calculations required to obtain ΔE_{00} energies from ΔE_{ve} ones. The results demonstrate that it is indeed possible to both closely (to within 0.06–0.08 eV) and consistently approximate ‘true’ CC2 ΔE_{00} energies in this way, especially when CC2 is combined with hybrid density functionals. Overall, the study highlights the unexploited potential of composite procedures, which hitherto have found widespread use mostly in ground-state chemistry, to also play an important role in facilitating accurate studies of excited states.

Keywords

excited states • quantum chemistry • 0–0 excitation energies • composite procedures

1. Introduction

A common approach for benchmarking the performance of quantum chemical methods in calculating electronically excited states of molecular systems is to focus on vertical excitation energies (ΔE_{ve}) and use as reference data either experimental absorption maxima or ΔE_{ve} energies obtained with high-level *ab initio* methods. Although this approach has been invaluable for establishing how well different methods in the field describe different types of excited states [1–7], it rests on two key assumptions. First, it is assumed that the nuclei remain fixed in their ground-state geometric configuration during the electronic transition (the Franck-Condon principle). Second, it is assumed that vibrational effects do not influence the positions of experimental absorption maxima. Also, when the reference data are taken from high-level calculations, it has to be presupposed that these are indeed accurate [2]. In a similar vein, the use of reference data from experimental spectra measured in solution calls for a treatment of solvent effects, which makes it less straightforward to directly assess the intrinsic quality of the quantum chemical description of an excited state. In this regard, gas-phase data are preferable for benchmarking purposes, despite the many methodological possibilities [8–10] to model solvatochromic shifts [11–14].

Instead of calculating ΔE_{ve} energies and comparing these with experimental absorption maxima, a few excited-state benchmarks have rather focused on adiabatic or 0–0 excitation energies [15–29], herein denoted ΔE_{ad} and ΔE_{00} , respectively. As illustrated in Figure 1, these are energy differences between ground and excited states at their respective equilibrium geometries, without (ΔE_{ad}) or with (ΔE_{00}) inclusion of the lowest vibrational level. Although increasing the computational cost by requiring excited-state geometry optimizations and frequency calculations to obtain zero-point vibrational energy (ZPVE) corrections, such studies are nowadays feasible for a wide variety of excited-state methods thanks to efficient implementations of analytic gradients [15,30–48]. In one of the first extensive ΔE_{00} -based benchmarks, Furche and co-workers [21] first surveyed high-resolution gas-phase experiments to compile a large set (91 molecules, 109 states) of ΔE_{00} energies, including both organic molecules and inorganic main-group and transition-metal compounds. Then, they tested how well these energies are reproduced by time-dependent density functional theory (TD-DFT) [49–56], using six different functionals, and two correlated *ab initio* methods: the approximate coupled-cluster singles and doubles (CC2)

[57] and second-order algebraic diagrammatic construction approximation (ADC(2)) [58,59] methods.

In light of the emphasis on relatively small molecules in Furche's study [21], another extensive ΔE_{00} -based benchmark by Hättig and co-workers [25] rather dealt with medium-sized and large organic molecules. For such systems, a similarly large set (66 states) of high-resolution gas-phase ΔE_{00} energies was assembled and used to assess the performance of TD-DFT with the B3LYP hybrid functional [60–62], CC2, ADC(2) and the spin-scaled SCS-CC2 and SOS-CC2 variants of CC2 [18,46,63]. Also recognizing the value of an investigation focused on larger molecules, Jacquemin and co-workers [23] considered a 40-member set of excited states of conjugated dyes, which they subjected to TD-DFT calculations exclusively. In contrast to the studies by Furche [21] and Hättig [25], however, these authors' interest lay in the reproducibility of experimental ΔE_{00} energies in solution, as determined from the intersection of measured absorption and fluorescence bands. This work was later followed by a second extensive ΔE_{00} -based study of medium-sized and large conjugated dyes in solution [29], but this time investigating the performance of *ab initio* methods like CC2 and ADC(2).

As shown by some research groups [64–73] but not easily afforded in broad benchmark studies, it is also possible to go beyond the ΔE_{00} description of excited states and successfully simulate – in both the gas phase and in solution – the full vibronic structure of an electronic absorption spectrum. Such simulations are very helpful for determining which type of transition (vertical or 0–0) best represents the experimental absorption maximum [68].

In a recent study, we contributed to the benchmarking of excited-state methods from a different angle. Namely, instead of primarily focusing our interest on the accuracy with which excited-state methods reproduce experimental absorption maxima or experimental ΔE_{00} energies, we investigated to what extent calculated *differences* between ΔE_{ve} , ΔE_{ad} and ΔE_{00} energies vary with the choice of method [26]. To the best of our knowledge, this was the first investigation of its kind to be reported for a large set of excited states and methods. Specifically, for a slightly reduced version of Furche's 109-member set of excited states [21], ΔE_{ve} , ΔE_{ad} and ΔE_{00} energies were calculated using TD-DFT with seven different functionals, CC2 and the configuration interaction singles (CIS) method [31]. Thereby, it was found that while the average standard deviations for the ΔE_{ve} , ΔE_{ad} and ΔE_{00} energies obtained with the nine methods amount to ~0.4 eV, the corresponding values for the $\Delta\Delta E_{ad} = \Delta E_{ad} - \Delta E_{ve}$ and $\Delta\Delta E_{00} = \Delta E_{00} - \Delta E_{ad}$ energy

differences are only 0.10 and 0.02 eV, respectively [26]. These results are a clear, quantitative indication that while calculating excitation energies is a notoriously challenging and method-dependent task in quantum chemistry, determining the photochemically relevant $\Delta\Delta E_{\text{ad}}$ (excited-state relaxation energy) and $\Delta\Delta E_{00}$ (difference in ZPVE corrections between the excited state and the ground state) quantities is much less sensitive to the choice of method.

A frequent observation regarding single-reference organic excited states in ΔE_{00} -based benchmarks is that TD-DFT, which is currently the most popular tool for modeling excited states, cannot fully match the performance of CC2 [25,26,29]. Indeed, for such states, CC2 typically shows excellent agreement (~ 0.1 eV) with experimental ΔE_{00} energies [25,26,29]. However, although CC2 is one of the most cost-effective approaches to account for dynamic electron correlation effects in excited states, it is still an expensive method compared to TD-DFT, especially when it comes to performing excited-state geometry optimizations and frequency calculations. Therefore, it is desirable to develop and assess computational procedures capable of yielding ΔE_{00} energies of CC2 quality at a lower cost, particularly for large molecules.

In this work, we investigate to what extent the aforementioned method-insensitivity of $\Delta\Delta E_{\text{ad}}$ and $\Delta\Delta E_{00}$ documented [26] for Furche’s benchmark set [21] of relatively small organic and inorganic molecules can be exploited to obtain CC2-quality ΔE_{00} energies for the medium-sized and large (up to 78 atoms) organic chromophores contained in Hättig’s benchmark set [25], *without* having to use CC2 for excited-state geometry optimizations and frequency calculations. Specifically, we explore how well ‘true’ CC2 ΔE_{00} energies, denoted $\Delta E_{00}(\text{CC2})$ and obtained using CC2 for *all* parts of the required calculations as (see Figure 1)

$$\Delta E_{00}(\text{CC2}) = \Delta E_{\text{ve}}(\text{CC2}) + \Delta\Delta E_{\text{ad}}(\text{CC2}) + \Delta\Delta E_{00}(\text{CC2}), \quad (1)$$

are approximated when CC2 is used for the ΔE_{ve} and $\Delta\Delta E_{\text{ad}}$ terms or the ΔE_{ve} term only, and a cheaper method ‘X’ is used to calculate the remaining term(s):

$$\Delta E_{00}(\text{CC2/X}') = \Delta E_{\text{ve}}(\text{CC2}) + \Delta\Delta E_{\text{ad}}(\text{CC2}) + \Delta\Delta E_{00}(\text{X}) \quad (2)$$

and

$$\Delta E_{00}(\text{CC2}/\text{X}'') = \Delta E_{\text{ve}}(\text{CC2}) + \Delta\Delta E_{\text{ad}}(\text{X}) + \Delta\Delta E_{00}(\text{X}), \quad (3)$$

respectively. To this end, we first calculate ΔE_{ve} , ΔE_{ad} and ΔE_{00} energies and the corresponding $\Delta\Delta E_{\text{ad}} = \Delta E_{\text{ad}} - \Delta E_{\text{ve}}$ and $\Delta\Delta E_{00} = \Delta E_{00} - \Delta E_{\text{ad}}$ energy differences for each of the 66 states in Hättig's benchmark set [25] using CC2 as well as TD-DFT with the BP86 [74,75], PBE0 [76], M06-2X [77], M06-HF [78], CAM-B3LYP [79] and ω B97X-D [80,81] functionals and CIS. Then, we evaluate how well $\Delta E_{00}(\text{CC2}/\text{X}')$ and $\Delta E_{00}(\text{CC2}/\text{X}'')$ approximate $\Delta E_{00}(\text{CC2})$ when the latter eight methods are combined with CC2 according to equations (2) and (3). Furthermore, besides identifying ways to simplify the calculation of accurate ΔE_{00} energies, we also present valuable new data on the performance of six other density functionals than B3LYP – the only functional hitherto applied to Hättig's benchmark set [25] – in calculating experimentally available gas-phase ΔE_{00} energies of organic chromophores.

Finally, we note that although the use of composite procedures that combine different quantum chemical methods to obtain reliable ΔE_{00} energies at a lower computational cost is not a new endeavor, with earlier contributions from Grimme [16,19,20], Hättig [25] and Jacquemin [29,82–84] and their co-workers, the merits of such procedures for studies of excited states are nonetheless much less explored than their usefulness for studies of electronic ground states, which is well-established, especially in the calculation of accurate thermochemistry [85–88]. Thus, a study like the present one is timely, particularly since it involves a set of excited states with quite uniform character that (as we will see) are similarly described by the methods considered and for which composite procedures therefore have the greatest potential. In this light, the study should be viewed as an extensive initial assessment of the merits of composite procedures under favorable circumstances, rather than as a broad test of the general applicability of these approaches to different kinds of excited states.

2. Computational details

2.1. Composition of the benchmark set

The 66-member set of excited states of organic molecules considered is presented in Table 1 and in Figures S1–S4 of the Supplemental data. For ease of presentation, the molecules were divided into two groups: group I (comprising aromatic heterocyclic compounds, shown in Figure S1) and group II (comprising aromatic [or aliphatic] hydrocarbons and substituted aromatic hydrocarbons, shown in Figure S3). For example, of biological relevance, group I includes three porphyrins, of which Zn-tetraphenylporphine (77 atoms) and tetraphenylporphine (78 atoms) are the largest systems in the study. Some of the 66 states pertain to different conformational isomers of the same chromophore, such as the 2^1A state of seven isomers of tryptamine (see Figure S2) and the 2^1A state of the *gauche* isomer and the $1^1A''$ state of the *anti* isomer of 3P-propionic acid (see Figure S4). In each of these cases, the assignment of the experimental ΔE_{00} energies to the different isomers was done already in Ref. [25] and the original experimental studies cited therein. Importantly, all of the 66 states are the lowest excited singlet state (S_1) of the chromophore/isomer in question, and can be described as originating from a one-electron excitation out of a closed-shell single-reference ground state (S_0). As such, the states are qualitatively well-described by the TD-DFT, CIS and CC2 methods employed in this work, and do not require a generally applicable excited-state method like complete active space second-order perturbation theory (CASPT2) [89,90] or multi-reference CI (MRCI) [91,92].

2.2. Electronic structure methods

To evaluate how accurately $\Delta E_{00}(\text{CC2}/X')$ and $\Delta E_{00}(\text{CC2}/X'')$ computed through equations (2) and (3) reproduce $\Delta E_{00}(\text{CC2})$ obtained through equation (1), ΔE_{ve} , ΔE_{ad} and ΔE_{00} energies and the corresponding $\Delta\Delta E_{\text{ad}} = \Delta E_{\text{ad}} - \Delta E_{\text{ve}}$ and $\Delta\Delta E_{00} = \Delta E_{00} - \Delta E_{\text{ad}}$ energy differences were calculated using nine different methods: BP86, B3LYP, PBE0, M06-2X, M06-HF, CAM-B3LYP, ω B97X-D, CIS and CC2. Throughout all calculations, the TZVP valence triple- ζ plus polarization basis set [93] was employed (as deemed appropriate from complementary calculations with the larger aug-cc-pVTZ basis set [94,95]). Thereby, the geometries, electronic energies and ZPVE corrections needed to obtain the ‘true’ ΔE_{ve} , ΔE_{ad} and ΔE_{00} energies at a particular level of theory were computed at that very level, with a few exceptions specified below. All CC2 calculations were carried out within the resolution-of-the-identity approximation, and with an auxiliary TZVP basis set [96]. The omission of diffuse functions

through calculations with the TZVP basis set is motivated by the observation in Ref. [25] that, for the same set of excited states but using different methods (see Introduction), the effect of such basis functions on electronic energies is consistently smaller than 0.06 eV at the triple- ζ level. This result reflects the compact valence character that these excited states exhibit. It should also be re-iterated that the main focus of this work is not to achieve the best possible agreement with experimental data, which would certainly require diffuse functions, but rather to compare $\Delta E_{00}(\text{CC2}/\text{X}')$ and $\Delta E_{00}(\text{CC2}/\text{X}'')$ with $\Delta E_{00}(\text{CC2})$ at a reasonable basis-set level.

All seven density functionals used are based on the generalized gradient approximation (GGA), and have shown good performance in many TD-DFT benchmarks [1,3,5–7]. BP86 is a pure GGA without any exact Hartree-Fock (HF) exchange in the exchange-correlation potential; B3LYP and PBE0 are global hybrid GGAs that include a fixed fraction of HF exchange (20% and 25%, respectively); M06-2X (54%) and M06-HF (100%) are global hybrid meta-GGAs from the Minnesota family of functionals [97] that additionally include a dependence on the kinetic energy density; and CAM-B3LYP and ω B97X-D are range-separated hybrid GGAs whose potentials have the correct long-range asymptotic behavior, owing to the inclusion of a variable amount of HF exchange (larger at long interelectronic distances) by means of a suitable [98,99] partitioning of the Coulomb operator into short-range and long-range parts.

ΔE_{ve} , ΔE_{ad} and ΔE_{00} energies were calculated in the following way. First, ground- and excited-state geometries were optimized with each of the nine methods using analytic gradients not only for the DFT, HF and CC2 [100] ground-state optimizations, but also for the TD-DFT [42], CIS [31] and CC2 [39] excited-state optimizations. Based on the resulting geometries, ground- and excited-state frequency calculations were then carried out to obtain ZPVE corrections for both states, and to confirm that the geometries exhibit real vibrational frequencies only and hence correspond to potential-energy minima. While the DFT, HF and CIS frequencies were calculated with analytic second-derivative methods, the TD-DFT and CC2 frequencies were determined through numerical differentiation of analytic gradients using finite differences. Finally, ΔE_{ve} energies were obtained by performing TD-DFT, CIS and CC2 excited-state singlepoint calculations on the DFT, HF and CC2 ground-state geometries, respectively. ΔE_{ad} energies, in turn, were obtained as (pure electronic) energy differences between ground and excited states at their respective equilibrium geometries, and ΔE_{00} energies were obtained by adding ZPVE corrections to the ΔE_{ad} energies.

As for the goal to derive the ‘true’ ΔE_{ve} , ΔE_{ad} and ΔE_{00} energies at a specific level of theory by executing all calculations of geometries, electronic energies and ZPVE corrections at that very level, this was achievable in all cases but for the CC2 ΔE_{00} energies of the five largest molecules in the benchmark set: porphycene, porphine, chlorin, Zn-tetraphenylporphine and tetraphenylporphine. For these molecules, it is simply too expensive to determine ZPVE corrections numerically at the CC2/TZVP level. Therefore, for porphycene, porphine and chlorin, the CC2 ground- and excited-state geometries and ZPVE corrections were calculated with a smaller auxiliary SVP basis set [96]. For Zn-tetraphenylporphine and tetraphenylporphine, however, numerical frequency calculations are not feasible with this basis set either. As a workaround, the CC2/TZVP ZPVE corrections for these two molecules were instead taken from B3LYP/TZVP calculations.

All calculations were carried out with the GAUSSIAN 09 [101] and TURBOMOLE 6.3 [102,103] (for CC2 calculations with the RICC2 module [104]) suites of programs.

3. Results and discussion

3.1. ΔE_{00} energies with different methods

Before analyzing how the $\Delta E_{00}(\text{CC2/X}')$ and $\Delta E_{00}(\text{CC2/X}'')$ energies of the 66 states compare to the $\Delta E_{00}(\text{CC2})$ energies obtained from CC2 calculations exclusively, it is worthwhile to first evaluate how accurately the nine methods considered reproduce the corresponding experimental ΔE_{00} energies by themselves. This is done in Table 2, which compares the full set of calculated ‘true’ ΔE_{00} energies for each method with the experimental data assembled by Hättig and co-workers [25]. Provided is also a statistical analysis of the results in terms of the methods’ mean absolute errors (MAEs), maximum absolute errors (MaxAEs) and mean signed errors (MSEs) relative to the experimental values.

Starting with the results over the full benchmark set, it is clear that none of the density functionals can rival the average accuracy and robustness achieved by CC2, whose MAE and MaxAE values amount to 0.11 and 0.22 eV, respectively. In terms of MAEs, the best-performing functionals are the B3LYP (0.20 eV) and PBE0 (0.24 eV) global hybrids, followed by the

ω B97X-D (0.32 eV) and CAM-B3LYP (0.33 eV) range-separated hybrids. The M06-2X and M06-HF meta-GGA global hybrids, in turn, have MAEs of 0.36 and 0.57 eV, respectively, that fall on either side of the 0.40 eV MAE shown by the pure BP86 functional. Thus, even though M06-HF through the inclusion of full HF exchange is more broadly applicable than B3LYP and PBE0 to different types of excited states – including Rydberg and charge-transfer states [77,78] that pose a considerable challenge to TD-DFT [52,55,105–108] – this functional is by some margin the least accurate functional for the current benchmark set of low-lying organic valence states. Since the MAE for M06-HF is 0.21 eV larger than the MAE for M06-2X (with 54% HF exchange), which in turn is 0.12–0.16 eV larger than the MAEs for PBE0 (25%) and B3LYP (20%), the inclusion of successively larger fractions of HF exchange beyond the B3LYP and PBE0 values appears to have a negative effect on the accuracy of calculated ΔE_{00} energies of such states.

Notably, it is well-documented that a 20–25% fraction of HF exchange in a hybrid functional is also what yields the best performance for the calculation of ΔE_{ve} energies of singlet organic valence states using TD-DFT [5], with increasing amounts of HF exchange typically having a blue-shifting effect. As can be inferred from the MSE values in Table 2, a similar effect is present in the calculation of ΔE_{00} energies. Specifically, the MSE is negative for BP86 (–0.39 eV), which thus tends to underestimate these ΔE_{00} energies, but increasingly positive for B3LYP (0.05 eV), PBE0 (0.16 eV), M06-2X (0.33 eV) and M06-HF (0.55 eV). For CIS, the MSE is a substantial 1.08 eV. On a positive note, however, CIS is the only method whose errors are ‘perfectly’ systematic, because the ΔE_{00} estimates are without exception larger than their experimental counterparts (i.e., MSE = MAE).

Given that the excited states are of valence type, it is perhaps not surprising that CAM-B3LYP and ω B97X-D show larger MAEs than B3LYP and PBE0, as the range separation of the Coulomb operator used in the former methods is primarily aimed at improving the description of long-range charge-transfer excitations [79–81]. It is possible that the CAM-B3LYP and ω B97X-D MAEs would have been smaller if, in a simplified computational procedure, the nine sets of ΔE_{00} energies had been obtained from nine sets of singlepoint calculations performed using a *common* set of geometries and ZPVE corrections (obtained with, e.g., B3LYP). In this regard, Rohrdanz and Herbert have shown that it is indeed difficult to assign a value to the range-separation parameter employed by range-separated functionals that is simultaneously suitable for

both excitation energies *and* ground-state properties [109]. Nonetheless, we believe that the most pertinent assessment of the ‘true’ performance of a method in calculating ΔE_{00} energies is to use the method not only for singlepoint calculations, but also for geometry optimizations and frequency calculations. Notably, although CAM-B3LYP and ω B97X-D have larger MAEs than B3LYP and PBE0, a comparison of the MaxAEs – 0.56 eV (CAM-B3LYP and ω B97X-D), 0.65 eV (PBE0) and 0.72 eV (B3LYP) – indicates that the former methods are more robust, albeit by no means as robust as CC2 (whose MaxAE is only 0.22 eV).

By comparing the overall MAEs for the full benchmark set with (also given in Table 2) the MAEs within groups I and II of the benchmark set, it is found that the overall CC2 > B3LYP/PBE0 > ω B97X-D/CAM-B3LYP > M06-2X/M06-HF > CIS performance ordering applies separately to these two groups as well. Also, with one notable exception, each method shows a smaller (by 0.03–0.16 eV) MAE for the heterocyclic compounds of group I, than for the hydrocarbons and substituted hydrocarbons of group II. The outlier in this pattern is BP86, whose MAE of 0.60 eV within group I is markedly larger than its MAE of 0.27 eV within group II. One strongly contributing factor to the large MAE of BP86 within group I, and thus to the comparatively poor performance of this method for the full benchmark set (MAE of 0.40 eV), is that it severely underestimates the ΔE_{00} energies of the 2^1A state of the seven different tryptamine isomers included in group I (see Figure S2). Specifically, for each of these isomers, BP86 underestimates the experimental ΔE_{00} energy by at least 1.15 eV. As a consequence, if the tryptamine isomers are excluded from the benchmark set, the group I and overall BP86 MAEs are reduced by 0.24 (from 0.60 to 0.36) and 0.10 (from 0.40 to 0.30) eV, respectively, whereas the corresponding MAEs of all other methods are affected by at most 0.03 and 0.02 eV, respectively. In fact, without tryptamine, the overall BP86 MAE of 0.30 eV is surpassed only by CC2 (0.11 eV), B3LYP (0.20 eV) and PBE0 (0.26 eV).

It is also worthwhile to compare the overall statistics for how well the nine methods employed in this work perform in calculating ΔE_{00} energies with the corresponding statistics documented in previous benchmarks investigating other methods and/or chemical systems. Comparing with the study by Hättig and co-workers [25], who considered the same exact 66-member set of organic excited states (but kept a clear focus on *ab initio* methods and carried out TD-DFT calculations with B3LYP alone), the present results reaffirm their finding that CC2 is favored over TD-DFT by at least ~ 0.1 eV for such systems. Comparing also with our own recent

results [26] for 96 excited states of smaller organic and inorganic compounds obtained with the same nine methods used herein, it is noteworthy that the present MAEs offer a ranking of the methods that is *identical* to the ranking offered by the MAEs found in that study: CC2 (0.11/0.19 eV), B3LYP (0.20/0.24), PBE0 (0.24/0.26), ω B97X-D (0.32/0.27), CAM-B3LYP (0.33/0.27), M06-2X (0.36/0.30), BP86 (0.40/0.42), M06-HF (0.57/0.50) and CIS (1.08/0.88) [26]. Accordingly, B3LYP and PBE0 appear especially suitable density functionals for calculating ΔE_{00} energies.

Finally, comparing with the TD-DFT benchmark by Jacquemin and co-workers [23], who considered 40 excited states of medium-sized and large conjugated dyes in solution, the 0.24 eV MAE of PBE0 reported in the present study is close to the value of 0.22 eV found in their study. For other functionals tested in both studies, the differences in MAEs are slightly larger: 0.20 vs. 0.27 eV for B3LYP; 0.33 vs. 0.25 eV for CAM-B3LYP; and 0.36 vs. 0.26 eV for M06-2X.

3.2. Performance of the composite procedures

We now turn to analyzing how well the $\Delta E_{00}(\text{CC2/X}')$ and $\Delta E_{00}(\text{CC2/X}'')$ energies, obtained by combining CC2 calculations with calculations using BP86, B3LYP, PBE0, M06-2X, M06-HF, CAM-B3LYP, ω B97X-D and CIS according to equations (2) and (3), approximate the ‘true’ $\Delta E_{00}(\text{CC2})$ energies obtained when CC2 is used for all parts of the required calculations. This is done in Figures 2 and 3, which respectively show the absolute errors (AEs) of $\Delta E_{00}(\text{CC2/X}')$ and $\Delta E_{00}(\text{CC2/X}'')$ relative to $\Delta E_{00}(\text{CC2})$ for each of the 66 states in the benchmark set.

Starting with the results for the $\Delta E_{00}(\text{CC2/X}')$ scheme in which TD-DFT or CIS replaces CC2 for the calculation of the $\Delta\Delta E_{00}$ term of $\Delta E_{00} = \Delta E_{\text{ve}} + \Delta\Delta E_{\text{ad}} + \Delta\Delta E_{00}$, Figure 2 shows that the AEs introduced by this procedure consistently average to very small values (MAEs of 0.03–0.04 eV) over the 66 states. Thus, for states of the current type it is generally possible to compute the expensive $\Delta\Delta E_{00}$ term with a cheap method, without it affecting the quality of the final ΔE_{00} energy.

Continuing with the results for the $\Delta E_{00}(\text{CC2/X}'')$ scheme in which also the $\Delta\Delta E_{\text{ad}}$ term is obtained with TD-DFT or CIS, Figure 3 reveals that the AEs remain small even after this step is taken. This holds true especially for the hybrid functionals (MAEs of 0.06–0.08 eV).

Accordingly, for a clear majority of the 66 states it is perfectly feasible to compute ΔE_{00} energies of CC2 quality by employing CC2 only for the vertical ΔE_{ve} term, and resorting to hybrid functionals for both the $\Delta \Delta E_{00}$ and $\Delta \Delta E_{ad}$ terms. This, we believe, is the first time that such a trend is extensively validated for a variety of different density functionals in one single study, and helps reinforce previous positive results on whether one specific functional can partly replace a correlated *ab initio* method in accurate ΔE_{00} calculations [25,29,82–84]. This also means that photochemical problems whose modeling requires reliable calculation of the $\Delta \Delta E_{00}$ and $\Delta \Delta E_{ad}$ terms, such as understanding isotope effects in excited states [110,111], are more well-suited for cheap methods than one may at first envision.

At this point, it may be re-emphasized that all three terms of $\Delta E_{00}(\text{CC2})$, $\Delta E_{00}(\text{CC2/X'})$ and $\Delta E_{00}(\text{CC2/X''})$ have consistently been calculated with a *single* basis set lacking diffuse functions (TZVP), without adopting the common practice to perform singlepoint calculations with a larger basis set. This procedure allows for a balanced comparison of $\Delta E_{00}(\text{CC2/X'})$ and $\Delta E_{00}(\text{CC2/X''})$ to $\Delta E_{00}(\text{CC2})$ at a reasonable basis-set level, and has been prioritized over comparing $\Delta E_{00}(\text{CC2/X'})$ and $\Delta E_{00}(\text{CC2/X''})$ to as accurate $\Delta E_{00}(\text{CC2})$ energies as possible. However, it is also of interest to use $\Delta E_{00}(\text{CC2})$ energies obtained with diffuse functions as reference. For the present benchmark set, such energies are available from Hättig's original study [25], which used the aug-cc-pVTZ basis set [94,95] for CC2 singlepoint calculations on CC2/TZVPP ground- and excited-state geometries. Since the $\Delta E_{ve}(\text{CC2})$ term needed to compute $\Delta E_{00}(\text{CC2/X'})$ and $\Delta E_{00}(\text{CC2/X''})$ is not included in the data reported by Hättig, this term was for each of the 66 states re-calculated using the aug-cc-pVTZ basis set, so as to enable an appropriate comparison with Hättig's $\Delta E_{00}(\text{CC2})$ energies. The results of this comparison are given in Table S1 of the Supplemental data. As can be seen, the MAEs of $\Delta E_{00}(\text{CC2/X'})$ and $\Delta E_{00}(\text{CC2/X''})$ relative to Hättig's $\Delta E_{00}(\text{CC2})$ energies are consistently very similar to the original MAEs obtained when all calculations are performed with the TZVP basis set, with a maximum discrepancy of 0.02 eV only. This is a clear indication that the conclusions drawn regarding the usefulness of the $\Delta E_{00}(\text{CC2/X'})$ and $\Delta E_{00}(\text{CC2/X''})$ schemes are not biased by the choice of basis set.

Returning to the results in Figures 2 and 3, there are also a few outlier states with quite large MaxAEs where especially the $\Delta E_{00}(\text{CC2/X''})$ scheme faces problems. Given the number of states considered, such outliers are expected and will be further discussed below. First, however, it is

pertinent to ask why $\Delta E_{00}(\text{CC2/X}')$ and $\Delta E_{00}(\text{CC2/X}'')$ are overall so surprisingly good approximations to $\Delta E_{00}(\text{CC2})$ for the current set of excited states. Of course, it should be clearly pointed out that we have deliberately focused our investigation on states with single-reference character whose descriptions by the different methods are (as we will see) qualitatively similar and for which composite procedures therefore have the greatest potential. Notwithstanding, an extensive quantitative assessment of the performance of composite procedures under these favorable circumstances is much desirable, before exploring their general applicability to more variable sets of excited states in future work.

From their very definitions, it follows directly that the reason why the $\Delta E_{00}(\text{CC2/X}')$ and $\Delta E_{00}(\text{CC2/X}'')$ schemes perform well is a lesser method-dependence in calculating $\Delta\Delta E_{\text{ad}}$ and $\Delta\Delta E_{00}$ values than in calculating the ΔE_{ve} , ΔE_{ad} and ΔE_{00} excitation energies themselves, which in turn stems from a systematic cancellation of errors. Thus, it is illuminating to establish these relationships quantitatively, which we have done in Figure 4 and Table 3 using the method-dependence of ΔE_{ve} as reference (we could just as well have used ΔE_{ad} or ΔE_{00} for this purpose; this choice does not affect the analysis). For each of the 66 excited states in the benchmark set, Figure 4 compares standard deviations $\sigma(X)$ (SDs), evaluated as

$$\sigma(X) = \sqrt{\frac{\sum (x - \bar{x})^2}{n}}, \quad (4)$$

for the calculated $\Delta\Delta E_{\text{ad}}$ and $\Delta\Delta E_{00}$ energy differences with the corresponding SD for the calculated ΔE_{ve} energies. In each case, the SDs pertain to the variation between all nine methods employed for the calculations. The raw data underlying the analysis are given in Tables S2 (group I of the benchmark set) and S3 (group II) of the Supplemental data. Table 3, in turn, lists the average SDs (denoted ASDs) for the ΔE_{ve} , $\Delta\Delta E_{\text{ad}}$ and $\Delta\Delta E_{00}$ calculations within groups I and II separately, and within the full benchmark set (i.e., groups I and II merged together). Thus, the ASDs in group I are obtained by averaging the SDs for all states in group I, and so on.

From Table 3, the ASD for the calculation of ΔE_{ve} energies is 0.39 eV for the full benchmark set, and is only slightly different in the two sub-groups: 0.41 eV for the heterocyclic compounds of group I and 0.38 eV for the hydrocarbons of group II. These values illustrate the

notorious method-dependency plaguing the calculation of molecular excitation energies in quantum chemistry. Notably, however, the ASDs for $\Delta\Delta E_{\text{ad}}$ and $\Delta\Delta E_{00}$ over the full benchmark set are markedly smaller, amounting to a mere 0.06 and 0.02 eV, respectively. The same goes for the corresponding ASDs over the individual sub-groups, which fall within 0.05–0.08 ($\Delta\Delta E_{\text{ad}}$) and 0.02–0.03 eV ($\Delta\Delta E_{00}$). These results solidify that accurate estimates of $\Delta\Delta E_{\text{ad}}$ and $\Delta\Delta E_{00}$ energy differences are well-amenable to cheap methods, which is why $\Delta E_{00}(\text{CC2/X}')$ and $\Delta E_{00}(\text{CC2/X}'')$ on the whole approximate $\Delta E_{00}(\text{CC2})$ so well.

It could be argued that it is more noteworthy that $\Delta\Delta E_{\text{ad}}$ varies little with the choice of computational method, than that the same holds true for $\Delta\Delta E_{00}$, which is simply the difference in ZPVE corrections between the excited state and the ground state. However, as shown on geometric grounds in Table S4 of the Supplemental data, there is a large degree of similarity between the methods in their descriptions of the excited states, enabled by the fact that all states have single-reference character, which helps explain why also the predicted $\Delta\Delta E_{\text{ad}}$ excited-state relaxation energies are similar.

Finally, it is also of interest to explore if certain criteria can be established that help anticipate beforehand whether the $\Delta E_{00}(\text{CC2/X}')$ and $\Delta E_{00}(\text{CC2/X}'')$ schemes can be successfully applied to a particular excited state, and that also help explain the origin of the aforementioned outlier states in Figures 2 and 3. An attempt to achieve this is reported in Figure S5 of the Supplemental data, focusing on the $\Delta E_{00}(\text{CC2/X}'')$ scheme (whose errors are larger). Specifically, first a subset of states was selected for which each state is such that the MAE relative to $\Delta E_{00}(\text{CC2})$ for the eight methods complementing CC2 in the $\Delta E_{00}(\text{CC2/X}'')$ scheme exceeds a certain threshold, as defined in the Supplemental data. Second, for each of these states, this MAE value, denoted MAE-X'', was associated with the corresponding geometric ‘similarity measures’ from Table S4 that quantify the variation in calculated excited-state bond lengths between the methods. Then, the MAE-X'' values were plotted as functions of these measures in Figure S5. Notably, with quite reasonable R^2 values of 0.72–0.77, the resulting plots indicate that $\Delta E_{00}(\text{CC2/X}'')$ will come close to $\Delta E_{00}(\text{CC2})$ provided that the methods yield similar geometries of the excited state in question. Thus, it appears useful to perform precisely this test before employing a composite procedure to estimate the ΔE_{00} energy of a single-reference organic excited state.

3.3. $\Delta\Delta E_{ad}$ and $\Delta\Delta E_{00}$ energy differences for different chemical systems

In this section we briefly assess how calculated $\Delta\Delta E_{ad}$ and $\Delta\Delta E_{00}$ energy differences vary from one chemical system to another, with some notable findings. Figure 5 shows histograms of the $\Delta\Delta E_{ad}$ and $\Delta\Delta E_{00}$ values obtained for the 66 states in the benchmark set. For each state, the histograms consider the average $\Delta\Delta E_{ad}$ and $\Delta\Delta E_{00}$ values for that state as obtained from nine separate sets of calculations using BP86, B3LYP, PBE0, M06-2X, M06-HF, CAM-B3LYP, ω B97X-D, CIS and CC2. Histograms for the individual methods are presented in Figures S6 and S7 of the Supplemental data. Since the statistics of these histograms are almost identical to what Figure 5 shows, they will not be discussed in further detail.

From Figure 5 (a), the variation in $\Delta\Delta E_{00}$ between the states is seen to be extraordinary small, with a SD of only 0.04 eV despite that a broad range of molecular sizes is covered (from 10 atoms in pyrazine to 78 atoms in tetraphenylporphine). The mean $\Delta\Delta E_{00}$ value for the 66 states is -0.14 eV, which, given the small SD, appears a very reasonable *a priori* estimate of this quantity for excited states of similar organic molecules that preclude quantum chemical investigation. Qualitatively, the clear tendency of $\Delta\Delta E_{00}$ to be negative (i.e, the tendency of ΔE_{00} excitation energies to be smaller than ΔE_{ad} ones) can be rationalized in terms of weakened bonding in the excited state, whereby the associated potential energy surface is flattened and the ZPVE correction reduced with respect to the situation in the ground state.

As for the $\Delta\Delta E_{ad}$ histogram in Figure 5 (b), finally, this negative quantity also shows surprisingly little variation between the states. Specifically, the SD amounts to 0.09 eV, which is larger than the variation in $\Delta\Delta E_{00}$, yet sufficiently small that the mean value of -0.24 eV holds some predictive power.

4. Conclusions

Benchmark studies are indispensable in computational chemistry for assessing the applicability of different methods in the field to different chemical problems. Calculating electronically excited states is one example where such studies are especially important, because of the many

challenges associated with describing excited states from first principles. In this work, we have contributed to the benchmarking of excited-state methods from a different angle than the usual one. Specifically, rather than having as main goal to assess how well different methods reproduce reference ΔE_{ve} or ΔE_{00} energies, we have explored the possibility to simplify the calculation of accurate ΔE_{00} energies by means of composite procedures. In these, a cheap method replaces a more expensive one for the cumbersome excited-state geometry optimizations and frequency calculations that are needed to estimate the $\Delta\Delta E_{\text{ad}}$ (excited-state relaxation energy) and $\Delta\Delta E_{00}$ (difference in ZPVE corrections between the excited state and the ground state) terms of $\Delta E_{00} = \Delta E_{\text{ve}} + \Delta\Delta E_{\text{ad}} + \Delta\Delta E_{00}$.

To this end and with the goal to reduce the cost to obtain ΔE_{00} energies of CC2 quality, we consider a benchmark set of 66 single-reference excited states of medium-sized and large organic molecules [25] and calculate the three different terms in ΔE_{00} using on the one hand CC2 and on the other less expensive TD-DFT (with the BP86, B3LYP, PBE0, M06-2X, M06-HF, CAM-B3LYP and ω B97X-D functionals) and CIS methods. Although composite procedures that combine different levels of theory are not a new idea in excited-state quantum chemistry [16,19,20,25,29,82–84], their applicability to excited states has not been as thoroughly explored as is the case for problems in ground-state chemistry, where such approaches are integral tools for, e.g., the calculation of accurate thermochemistry [85–88].

The resulting data show that it is perfectly possible to replace CC2 with TD-DFT or CIS for the $\Delta\Delta E_{00}$ part of the calculations, without deteriorating the quality of the final ΔE_{00} energy. Indeed, irrespective of which of the alternative eight methods is invoked for this part, the MAE of the corresponding ΔE_{00} energies for the 66 states relative to the ΔE_{00} energies obtained when CC2 is used for all parts of the calculations, is consistently a mere 0.03–0.04 eV. Furthermore, the MAEs remain small even when also the $\Delta\Delta E_{\text{ad}}$ term is computed with TD-DFT or CIS instead of CC2, particularly so for the hybrid functionals (MAEs of 0.06–0.08 eV). In fact, for a clear majority of the 66 states CC2-quality ΔE_{00} energies can be calculated by employing CC2 only for the vertical ΔE_{ve} term, and using any of the hybrid functionals for both of the $\Delta\Delta E_{\text{ad}}$ and $\Delta\Delta E_{00}$ terms. To the best of our knowledge, this is the first time that such a trend is supported by computational evidence derived for both a statistically meaningful number of chemical systems and a variety of different density functionals.

Having thus demonstrated the potential of composite procedures for studies of single-reference organic excited states, it is a natural goal of future research in the field to also test the performance of composite procedures that combine more versatile methods than CC2 and TD-DFT for applications to sets of more variable and challenging types of excited states. Relevant systems that come to mind are, for example, excited states of transition-metal compounds [112] and polar intramolecular charge-transfer excited states of dual-fluorescent aromatic compounds [113].

Through the calculations, we have also been able to present valuable new benchmark data on how closely TD-DFT, CIS and CC2 reproduce experimentally available ΔE_{00} energies of organic chromophores, when the ΔE_{00} energies produced by each method are exclusively based on geometries, electronic energies and ZPVE corrections computed with that method. Thereby, CC2 is found to yield impressively accurate and robust results, with MAE and MaxAE values of only 0.11 and 0.22 eV, respectively. With a MAE of 0.20 eV, the best-performing functional is B3LYP, followed by PBE0 (0.24 eV), ω B97X-D (0.32 eV) and CAM-B3LYP (0.33 eV).

Finally, it is also found that the $\Delta\Delta E_{\text{ad}}$ and $\Delta\Delta E_{00}$ quantities vary remarkably little from one system in the benchmark set to another. Actually, the SD for the $\Delta\Delta E_{00}$ values of the 66 states is only 0.04 eV, which means that this quantity falls within a very narrow range around the mean value of -0.14 eV. This mean value can therefore be regarded as a ‘typical’ $\Delta\Delta E_{00}$ value for these *and* similar systems. Equaling 0.09 eV, the SD for the $\Delta\Delta E_{\text{ad}}$ values is also small.

Table 1. Groups (I and II) of molecules and excited states in the benchmark set.^a

Group I ^b	Label ^c	State	Group II ^d	Label ^c	State
pyrazine	1	S ₁ 1 ¹ A _u	tetrafluorobenzene	1	S ₁ 1 ¹ B ₁
2,6-difluoropyridine	2	S ₁ 1 ¹ B ₂	benzonitrile	2	S ₁ 1 ¹ B ₂
2-fluoropyridine	3	S ₁ 2 ¹ A'	<i>o</i> -fluorophenol, <i>cis</i>	3	S ₁ 2 ¹ A
2-hydroxypyridine	4	S ₁ 2 ¹ A'	<i>o</i> -fluorophenol, <i>trans</i>	4	S ₁ 2 ¹ A
2-pyridone	5	S ₁ 2 ¹ A'	<i>m</i> -fluorophenol, <i>cis</i>	5	S ₁ 2 ¹ A
2-methylpyrimidine	6	S ₁ 1 ¹ A''	<i>m</i> -fluorophenol, <i>trans</i>	6	S ₁ 2 ¹ A'
5-methylpyrimidine	7	S ₁ 1 ¹ A''	<i>p</i> -fluorophenol	7	S ₁ 2 ¹ A'
7-azaindole	8	S ₁ 2 ¹ A'	phenylacetylene	8	S ₁ 1 ¹ B ₂
7-hydroxyquinoline, <i>cis</i>	9	S ₁ 2 ¹ A'	aniline	9	S ₁ 1 ¹ A''
7-hydroxyquinoline, <i>trans</i>	10	S ₁ 2 ¹ A	catechol	10	S ₁ 2 ¹ A
2-hydroxyquinoline, enol	11	S ₁ 2 ¹ A'	resorcinol, isomer 1	11	S ₁ 2 ¹ A
2-hydroxyquinoline, keto	12	S ₁ 2 ¹ A'	resorcinol, isomer 2	12	S ₁ 1 ¹ B ₂
dibenzofuran	13	S ₁ 2 ¹ A ₁	resorcinol, isomer 3	13	S ₁ 1 ¹ A''
pyrrolo[3,2- <i>h</i>]quinoline	14	S ₁ 2 ¹ A'	hydroquinone, <i>cis</i>	14	S ₁ 2 ¹ A ₁
carbazole	15	S ₁ 2 ¹ A ₁	hydroquinone, <i>trans</i>	15	S ₁ 1 ¹ B _u
tryptamine, A-ph ^e	16	S ₁ 2 ¹ A	salicylic acid	16	S ₁ 2 ¹ A'
tryptamine, A-py ^f	17	S ₁ 2 ¹ A	<i>o</i> -cresol, <i>cis</i>	17	S ₁ 2 ¹ A
tryptamine, A-up ^g	18	S ₁ 2 ¹ A	<i>o</i> -cresol, <i>trans</i>	18	S ₁ 2 ¹ A
tryptamine, Ph-out ^h	19	S ₁ 2 ¹ A	<i>m</i> -cresol, <i>cis</i>	19	S ₁ 2 ¹ A
tryptamine, Ph-up ⁱ	20	S ₁ 2 ¹ A	<i>m</i> -cresol, <i>trans</i>	20	S ₁ 2 ¹ A'
tryptamine, Py-out ^j	21	S ₁ 2 ¹ A	<i>p</i> -cresol	21	S ₁ 2 ¹ A
tryptamine, Py-up ^k	22	S ₁ 2 ¹ A	<i>o</i> -methoxyphenol	22	S ₁ 2 ¹ A
porphycene	23	S ₁ 2 ¹ A'	<i>m</i> -methoxyphenol, isomer 1	23	S ₁ 2 ¹ A
porphine	24	S ₁ 1 ¹ B _{1u}	<i>m</i> -methoxyphenol, isomer 2	24	S ₁ 2 ¹ A
chlorin	25	S ₁ 1 ¹ B ₂	<i>p</i> -methoxyphenol, <i>cis</i>	25	S ₁ 2 ¹ A
Zn-tetraphenylporphine	26	S ₁ 1 ¹ B ₂	<i>p</i> -methoxyphenol, <i>trans</i>	26	S ₁ 2 ¹ A
tetraphenylporphine	27	S ₁ 1 ¹ B	1-naphthol, <i>cis</i>	27	S ₁ 2 ¹ A
			1-naphthol, <i>trans</i>	28	S ₁ 2 ¹ A'
			2-naphthol, <i>cis</i>	29	S ₁ 2 ¹ A'
			2-naphthol, <i>trans</i>	30	S ₁ 2 ¹ A'
			5-methoxysalicylic acid	31	S ₁ 2 ¹ A'
			<i>m</i> -dimethoxybenzene, <i>trans</i>	32	S ₁ 2 ¹ A'
			3P-propionic acid, ^l <i>gauche</i>	33	S ₁ 2 ¹ A
			3P-propionic acid, ^l <i>anti</i>	34	S ₁ 1 ¹ A''
			fluorene	35	S ₁ 1 ¹ B ₂
			phenanthrene	36	S ₁ 2 ¹ A ₁
			2,4,6,8-decatetraene	37	S ₁ 1 ¹ B _u
			tetracene	38	S ₁ 1 ¹ B _{1u}
			perylene	39	S ₁ 1 ¹ B

^aThe molecules in groups I and II are depicted in Figures S1 and S3 of the Supplemental data. Symmetry labels reflect molecular geometries after excited-state relaxation. ^bGroup I: aromatic heterocyclic compounds. ^cLabel used in subsequent figures. ^dGroup II: aromatic (or aliphatic) hydrocarbons and substituted aromatic hydrocarbons. ^e*Anti*-ph. ^f*Anti*-py. ^g*Anti*-up. ^h*gauche*-phenyl-out. ⁱ*gauche*-phenyl-up. ^j*gauche*-pyrrole-out. ^k*gauche*-pyrrole-up. ^l3-phenyl-1-propionic acid.

Table 2. Calculated ΔE_{00} energies for all states in the benchmark set (eV).

Group I

*Different tryptamine isomers are shown in Figure S2.

Figure S1. Chemical structures of the molecules in group I of the benchmark set (continued on page S4).

Group I continued

chlorin

Zn-tetraphenylporphine

tetraphenylporphine

Figure S1. Continued.

Figure S2. Different tryptamine isomers.

Group II

Figure S3. Chemical structures of the molecules in group II of the benchmark set (continued on page S7).

Group II continued

*Different 3P-propionic acid isomers are shown in Figure S4.

Figure S3. Continued.

3P-propionic acid, *gauche*

3P-propionic acid, *anti*

Figure S4. Different 3P-propionic acid isomers.

Figure S5. MAE-X'' values as functions of $A_{\text{BLSD-S}_1}$ and $A_{\text{BLSD-S}_1\text{S}_0}$ values (see Table S4) for selected states in the benchmark set.

Comments on Figure S5

In order to make possible trends more easily discernible, the analysis in Figure S5 only includes states in the benchmark set whose MAE-X'' values are larger than a specific threshold value. This threshold value was defined as the average MAE for the eight $\Delta E_{00}(\text{CC2/X}'')$ schemes in Figure 3, and amounts to 0.078 eV.

Figure S6. Histograms of calculated $\Delta\Delta E_{00}$ energy differences at different levels of theory.

Figure S7. Histograms of calculated $\Delta\Delta E_{ad}$ energy differences at different levels of theory.

Table S1. Comparison of MAE and MaxAE values for the $\Delta E_{00}(\text{CC2}/\text{X}')$ and $\Delta E_{00}(\text{CC2}/\text{X}'')$ schemes relative to the $\Delta E_{00}(\text{CC2})$ energies reported in this work and by Hättig (eV).

^a $\Delta\Delta E_{ad} = \Delta E_{ad} - \Delta E_{ve}$ and $\Delta\Delta E_{00} = \Delta E_{00} - \Delta E_{ad}$. ^bStandard deviation (SD) and maximum absolute deviation (MaxAD) for calculations with the nine methods.

Table S4. $\langle A_{\text{BLSD-S}_1} \rangle$, $\langle A_{\text{BLSD-S}_1\text{S}_0} \rangle$ and $\langle A_{\text{BLSD-S}_0} \rangle$ values for bonds between heavy atoms for selected states in groups I and II of the benchmark set (Å).^a

Group(s) ^b	$\langle A_{\text{BLSD-S}_1} \rangle$	$\langle A_{\text{BLSD-S}_1\text{S}_0} \rangle$	$\langle A_{\text{BLSD-S}_0} \rangle$
I	0.013	0.013	0.007
II	0.009	0.009	0.007
I–II	0.011	0.010	0.007

^aAverage ASDs for excited-state bond lengths ($\langle A_{\text{BLSD-S}_1} \rangle$), for excited-state bond lengths relative to ground-state bond lengths ($\langle A_{\text{BLSD-S}_1\text{S}_0} \rangle$), and for ground-state bond lengths ($\langle A_{\text{BLSD-S}_0} \rangle$) with calculations performed using the BP86, B3LYP, PBE0, M06-2X, M06-HF, CAM-B3LYP, ω B97X-D, CIS and CC2 methods. ^bFrom group I, the states considered in the analysis are the S_1 states of pyrazine, 2,6-difluoropyridine, 2-pyridone, 2-methylpyrimidine, 7-azaindole, 7-hydroxyquinoline (*cis*), dibenzofuran, pyrrolo[3,2-*h*]quinoline, carbazole, tryptamine (A-ph) and porphycene. From group II, the states considered in the analysis are the S_1 states of tetrafluorobenzene, benzonitrile, *o*-fluorophenol (*cis*), phenylacetylene, aniline, catechol, resorcinol (isomer 1), hydroquinone (*cis*), salicylic acid, *o*-cresol (*cis*), *o*-methoxyphenol, 1-naphthol (*cis*), 5-methoxysalicylic acid, *m*-dimethoxybenzene (*trans*), 3P-propionic acid (*gauche*), fluorene, phenanthrene, 2,4,6,8-decatetraene, tetracene and perylene.

Comments on Table S4

The similarity between the methods (BP86, B3LYP, PBE0, M06-2X, M06-HF, CAM-B3LYP, ω B97X-D, CIS and CC2) in their descriptions of the excited states in the benchmark set was quantified geometrically in the following way. First, for a representative subset of excited states (see footnote [b]), SDs were computed for the estimates of each excited-state bond length, as well as for the estimates of each excited-state bond length relative to the corresponding ground-state bond length. Throughout, only bonds between heavy atoms were considered. Then, by averaging the resulting SDs over all bonds in the excited state in question, average bond-length SDs denoted $A_{\text{BLSD-S}_1}$ and $A_{\text{BLSD-S}_1\text{S}_0}$, respectively, were obtained for that excited state. Finally, by averaging the $A_{\text{BLSD-S}_1}$ and $A_{\text{BLSD-S}_1\text{S}_0}$ values over all excited states considered, ‘similarity measures’ denoted $\langle A_{\text{BLSD-S}_1} \rangle$ and $\langle A_{\text{BLSD-S}_1\text{S}_0} \rangle$, respectively, were obtained. These are the values given in Table S4. Notably, their smallness (0.011 and 0.010 Å for the full subset of excited states) are indicative of a large degree of similarity between the descriptions of the excited states by the methods, which helps explain why also the estimates of $\Delta\Delta E_{\text{ad}}$ are similar.
