Multiple viruses are widely studied because of their negative effect on the health of host as well as on whole population. The dynamics of coinfection are important in this case. We formulated an susceptible infected recovered (SIR) model that describes the coinfection of the two viral strains in a single host population with an addition of limited growth of susceptible in terms of carrying capacity. The model describes five classes of a population: susceptible, infected by first virus, infected by second virus, infected by both viruses, and completely immune class. We proved that for any set of parameter values, there exists a globally stable equilibrium point. This guarantees that the disease always persists in the population with a deeper connection between the intensity of infection and carrying capacity of population. Increase in resources in terms of carrying capacity promotes the risk of infection, which may lead to destabilization of the population.

carrying capacity, coinfection, global stability, linear complementarity problem, SIR model

---

**1 | INTRODUCTION**

Coinfection with multiple strains in a single host is very common. Viral diseases such as AIDS/ HIV, dengue fever, and hepatitis B and C are the great threats to human lives. Multiple strains of these viruses made the disease more severe and complicated to control. Sometimes, coinfection may occur with multiple disease in one host such as HIV and hepatitis B,1,2 HIV and hepatitis C,3 malaria and HIV,4 DENV and ZIKV,5 and ZIKV and CHIKV.6

Mathematical modelling of infectious diseases is an efficient tool for studying the dynamics of various virulent diseases, which benefits to develop the appropriate strategies to control possible outbreaks of diseases. One of the most significant aspects of studying multistrain epidemic models is to identify those conditions that lead to the coexistence of different strains. The dynamics of coinfection are important in this case, because in case of co-infection, treatment against one strain may agitate the other.7

Many mathematical studies exist on interaction of multiple strains such as dengue virus,6,9 influenza,10 and human papilloma virus11 and multiple diseases such as HIV/malaria,12 HIV/pneumonia,13,14 and malaria/cholera.15 Allen et al16 studied an SIR model with density-dependent mortality and coinfection in a single host where one strain is vertically transmitted and the other is horizontally transmitted. The model has application on hantavirus and arenavirus. An ordinary differential equations (ODEs) model of coinfection was designed by Zhang et al17 to study two parasite strains on two different hosts to know the sustainability and proliferation of these strains in response to variability in mode of action of
parasites and its host types. Bichara et al\textsuperscript{18} proposed Susceptible Infected Susceptible (SIS), SIR, and MSIR models with variable population and \( n \) different pathogen strains to study that under generic conditions, a competitive exclusion principle holds. A two-disease model was also used by Martcheva and Pilyugin\textsuperscript{19} to study dynamics of dual infection by considering time of infection of primary disease.

Castillo et al\textsuperscript{20} analysed an SIS model on sexually transmitted disease by two hostile strains. Females with different susceptibility level to any of the virulent strain were separated into two groups. Stability analysis was performed to identify conditions for the coexistence and competitive exclusion of the two strains. Gao et al\textsuperscript{7} study an SIS model with dual infection. Simultaneous transmission of infection and no immunity have been considered. The study revealed that the coexistence of multiple agents caused coinfection and made the disease dynamics more complicated. It was observed that coexistence of two disease can only occur in the presence of coinfection. In the above models, they considered that the number of births per unit time is constant.

Sharp and Pastor\textsuperscript{21} proposed a model for chronic wasting disease with density dependence to study the effect of density dependence and time delay on wildlife population and observed that more frequent outbreaks of disease are caused by increased carrying capacity, which leads to the disruption of a deer population. In contrast to the previous studies, we formulate an SIR model with coinfection and limited growth of susceptible population to study the effects of carrying capacity on disease dynamics. We also carried out global stability analysis using a generalized Volterra function for each stable point to study the complete dynamics of disease. The model was formulated, and some of our results were recently announced in Ghersheen et al.\textsuperscript{22} We analyse the model with the possibility of transmission of two strains simultaneously. However, contrary to Gao et al,\textsuperscript{7} to diminish the complexity of model and to study the global behaviour of the system, the reduction of the system is needed to some sense. So we assume that there is no interaction between single strains, since the coinfected class is always the largest class. Our model also includes the fact that coinfection can occur as a result of interaction between coinfected class and single-infected class and coinfected class and susceptible class. We analyse an SIR model with cross immunity. In Sections 3 and 9, we characterize all stable equilibrium points and give the results regarding global stability of all equilibrium points. In Section 10, we analyse the effect of carrying capacity on disease dynamics.

2 | FORMULATION OF THE MODEL

We consider an SIR model with the recovery of each class and assume that infected and recovered populations cannot reproduce. A susceptible individual can be infected with both stains as a result of contact with coinfecte person. The disease-induced death rate is ignored. We also assume that the coinfection can occur as a result of contact with the coinfected class. This process is illustrated in Figure 1.

![Flow diagram for two strains coinfection model](image-url)
The corresponding SIR model is then described by the ODE system as follows:

\[
\begin{align*}
S' &= \left( b \left( 1 - \frac{S}{K} \right) - \alpha_1 I_1 - \alpha_2 I_2 - \alpha_3 I_{12} - \mu_0 \right) S, \\
I_1' &= (\alpha_1 S - \eta_1 I_{12} - \mu_1) I_1, \\
I_2' &= (\alpha_2 S - \eta_2 I_{12} - \mu_2) I_2, \\
I_{12}' &= (\alpha_3 S + \eta_1 I_1 + \eta_2 I_2 - \mu_3) I_{12}, \\
R' &= \rho_1 I_1 + \rho_2 I_2 + \rho_3 I_{12} - \mu_R R.
\end{align*}
\]

Here and in what follows, we use the following notation:

- \( S \) represents the susceptible class,
- \( I_1 \) and \( I_2 \) represent infected classes from strains 1 and 2, respectively,
- \( I_{12} \) represents coinfected class,
- \( R \) represents the recovered class,
- \( b \) is the birth rate in the population,
- \( K \) is a carrying capacity,
- \( \rho_i \) is the recovery rate from infected class \( i \),
- \( \mu_i \) is the reduced death rate of class \( i \),
- \( \alpha_i \) is the transmission rate of strain \( i \) (including the case of coinfection), and
- \( \eta_i \) is rate at which infected from one strain getting infection from coinfected class \( i \).

Let us make some natural comments about the present model. First, we suppose (and it also follows from 1) that there is no interaction between strains 1 and 2. According to the definition of the SIR model given in Britton,\(^{23}\) the individuals upon recovery leave the infected class and do not play any further role in the dynamics. This is the main characteristic of this type of compartmental model. We follow this definition and assume that the population carry life-long immunity to a disease upon recovery, so that \( R \) variable is not presented in first four equations.

Note also that, to make mathematical analysis easy, we combine the terms \( \rho_i + \mu'_i \), \( i = 1, 2, 3 \), where \( \mu'_i \) is proper death rates of class \( i \), and denote them by \( \mu_i \). It is also reasonable to assume that the death rate of the susceptible class is less or equal than the corresponding reproduction rate because otherwise, population will die out quickly. Therefore, we assume always that

\[
b - \mu_0 > 0.
\]

Furthermore, the system is considered under the natural initial conditions

\[
S(0) > 0, \quad I_1(0) > 0, \quad I_2(0) > 0, \quad I_{12}(0) > 0.
\]

Indeed, it follows from the general theory of (1) that (a) any integral curve with (3) is staying in the non-negative cone for all \( t \geq 0 \) and, moreover, (b) if \( S(0) = 0 \) or \( I_a(0) = 0 \), for some index \( a \), then the corresponding coordinate will vanish for all \( t \geq 0 \).

Finally, note also that since the variable \( R \) is not presented in the first four equations, we may consider only the first four equations of system (1). Then, \( R(t) \) can be easily found by integrating the last (linear in \( R \)) equation in (1).

To make a rigorous mathematical analysis of (1), it is convenient to keep the following unifying notation:

\[
S = Y_0, \quad I_1 = Y_1, \quad I_2 = Y_2, \quad I_{12} = Y_3.
\]

Then, the first four equations of (1) can be rewritten in a compact Lotka-Volterra-type form:

\[
\frac{dY_k}{dt} = F_k(Y) \cdot Y_k, \quad k = 0, 1, 2, 3,
\]

where we denote

\[
F(Y) = -q + AY,
\]

with

\[
F(Y) = \begin{pmatrix} F_0(Y) \\ F_1(Y) \\ F_2(Y) \\ F_3(Y) \end{pmatrix}, \quad q = \begin{pmatrix} -b + \mu_0 \\ \mu_1 \\ \mu_2 \\ \mu_3 \end{pmatrix}, \quad A = \begin{pmatrix} -\frac{b}{K} & -\alpha_1 & -\alpha_2 & -\alpha_3 \\ \alpha_1 & 0 & 0 & -\eta_1 \\ \alpha_2 & 0 & 0 & -\eta_2 \\ \alpha_3 & \eta_1 & \eta_2 & 0 \end{pmatrix}, \quad Y = \begin{pmatrix} Y_0 \\ Y_1 \\ Y_2 \\ Y_3 \end{pmatrix}.
\]
A point \( Y = (Y_0, Y_1, Y_2, Y_3) \) is called an equilibrium point of (4) if
\[
Y_i F_i(Y) = 0, \quad 0 \leq i \leq 3. \tag{7}
\]
The following ratios play an essential role in our analysis:
\[
\sigma_i := \frac{\mu_i}{\alpha_i}, \quad 1 \leq i \leq 3.
\]
We shall always assume that the strains 1 and 2 are different in the sense \( \sigma_1 \neq \sigma_2 \). Indeed, if \( \sigma_1 = \sigma_2 \), it follows from the second and the third equations in (1) that the behaviour of the system lose the structural stability (ie, the qualitative picture drastically depends on small perturbations of the system parameters, in our case on the relations between \( \alpha_i, \mu_i, \) and \( \eta_i \)).

Then, by change of the indices (if needed), we may assume that
\[
\sigma_1 < \sigma_2. \tag{8}
\]
In other words, (8) means that strain 1 is more aggressive than strain 2. Furthermore, it is natural to assume that the transmission rate of coinfection is always less than the transmission rates of the viruses 1 and 2, while the death rates \( \mu_i \) are almost the same for different classes (as population groups). This makes it natural to assume the following hypotheses:
\[
\sigma_1 < \sigma_2 < \sigma_3. \tag{9}
\]

The vector of fundamental parameters
\[
p = (b, K, \mu_i, \alpha_j, \eta_k) \in \text{int}(\mathbb{R}_{++}^5), \quad \text{where } 0 \leq i \leq 3, \ 1 \leq j \leq 3, \ 1 \leq k \leq 2. \tag{10}
\]
is said to be admissible if (9) holds.

A fundamentally important parameter for our study is the modified carrying capacity defined by
\[
S_2 := K(1 - \frac{\mu_0}{b}) > 0. \tag{11}
\]
Note that the modified carrying capacity is always less than the carrying capacity. It expresses the (susceptible) population size in absence of any infection. More precisely, it follows from (1) that
\[
E_2 := (S_2, 0, 0, 0),
\]
is an equilibrium point. Then, \( E_2 \) represents the “healthy” state*, ie, the equilibrium state with no infection and coinfection.

3 | EQUILIBRIUM POINTS

Below, we use the standard vector order relation: given \( x, y \in \mathbb{R}^n \),

- \( x \leq y \) if \( x_i \leq y_i \) for all \( 1 \leq i \leq n \),
- \( x < y \) if \( x \leq y \) and \( x \neq y \), and
- \( x \ll y \) if \( x_i < y_i \) for all \( i \).

Then, \( \mathbb{R}_+^n \) denotes the nonnegative cone \( \{ x \in \mathbb{R}^n : x \geq 0 \} \) and for \( a \leq b, a, b \in \mathbb{R}^n, [a, b] = \{ x \in \mathbb{R}^n : a \leq x \leq b \} \) is the closed box with vertices at \( a \) and \( b \). By \( \mathbf{0} \), we denote the origin in \( \mathbb{R}^n \).

By \( \mathcal{E}(p) \), we denote the set of the equilibrium points of (4) with nonnegative coordinates, ie, those \( Y^* = (Y^*_0, Y^*_1, Y^*_2, Y^*_3) \geq 0 \) satisfying
\[
Y_i^* F_i(Y^*) = 0, \quad 0 \leq i \leq 3. \tag{12}
\]

One always has the trivial equilibria
\[
E_1 := \mathbf{0} \in \mathcal{E}(p),
\]

*To explain the notation, we denote by \( E_1 = \mathbf{0} \), the trivial equilibrium point, and by \( E_2 \), the first nontrivial equilibrium state; see also (34) below.
and the healthy equilibrium state

\[ E_2 \in \mathcal{E}(p), \]

so that \( \mathcal{E}(p) \) is always nonempty. The lemma below shows that the value of the susceptible class \( Y_0^* \) for the healthy equilibrium state \( E_2 \) is the largest possible among all equilibrium points \( Y^* \).

**Lemma 1.** If \( Y^* \neq 0 \) is an element of \( \mathcal{E}(p) \), then

\[ 0 < Y_0^* \leq S_2, \tag{13} \]

where the (above) equality holds if and only if \( Y_1^* = Y_2^* = Y_3^* = 0 \). Furthermore,

\[ \sigma_1 \leq Y_0^* \leq \min\{S_2, \sigma_3\}, \tag{14} \]

unless \( Y^* = (S_2, 0, 0, 0) \). Also, the following balance relations hold

\[ \begin{align*}
\alpha_1 Y_1^* + \alpha_2 Y_2^* + \alpha_3 Y_3^* &= \frac{b}{K} (S_2 - Y_0^*), \tag{15} \\
\mu_1 Y_1^* + \mu_2 Y_2^* + \mu_3 Y_3^* &= \frac{b}{K} (S_2 - Y_0^*) Y_0^*. \tag{16}
\end{align*} \]

In particular,

\[ \max_{0 \leq i \leq 3} Y_i^* \leq \frac{b}{K} \max \left\{ \frac{1}{\alpha_1}, \frac{1}{\alpha_2}, \frac{1}{\alpha_3}, b - \mu_0 \right\}. \tag{17} \]

**Proof.** Suppose first that \( Y^* \neq 0 \) and \( Y_0^* = 0 \). If \( Y_1^* \neq 0 \), then \( Y^*_3 = -\mu_1/\eta_1 < 0 \), a contradiction. Therefore, \( Y_1^* = 0 \). For the same reason, \( Y_2^* = 0 \). Therefore, it must be \( Y_3^* \neq 0 \). But in that case, it follows from the last equation in (12) by virtue of \( Y_3^* = Y_2^* = 0 \) that \( -\mu_3 = 0 \), a contradiction also. Therefore, \( Y_0^* \neq 0 \); thus, it is positive, which proves the left inequality in (13). Next, since \( Y_0^* \neq 0 \), the relation (15) follows immediately from the first equation in (12). Also, summing all the four equations in (12) yields (16). Next, since \( Y_i^* \geq 0 \), it follows from (16) that \( S_2 - Y_0^* \geq 0 \), which proves the second inequality in (13). Finally, if \( Y^* \geq 0 \), then dividing (16) by (15), we obtain

\[ Y_0^* = \frac{\mu_1 Y_1^* + \mu_2 Y_2^* + \mu_3 Y_3^*}{\alpha_1 Y_1^* + \alpha_2 Y_2^* + \alpha_3 Y_3^*}. \tag{18} \]

The latter expression is the ratio of two linear functions with positive coefficients. It is also zero degree homogeneous; hence, its maximal/minimal values are attained at the simplex \( \Pi := \alpha_1 Y_1^* + \alpha_2 Y_2^* + \alpha_3 Y_3^* = 1 \). It follows from the linearity of the numerator that

\[ \max_{\Pi} \frac{\mu_1 Y_1^* + \mu_2 Y_2^* + \mu_3 Y_3^*}{\alpha_1 Y_1^* + \alpha_2 Y_2^* + \alpha_3 Y_3^*} = \max_{\Pi} (\mu_1 Y_1^* + \mu_2 Y_2^* + \mu_3 Y_3^*) = \max \left\{ \frac{\mu_1}{\alpha_1}, \frac{\mu_2}{\alpha_2}, \frac{\mu_3}{\alpha_3} \right\} = \sigma_3, \]

and similarly

\[ \min_{\Pi} \frac{\mu_1 Y_1^* + \mu_2 Y_2^* + \mu_3 Y_3^*}{\alpha_1 Y_1^* + \alpha_2 Y_2^* + \alpha_3 Y_3^*} = \min_{\Pi} (\mu_1 Y_1^* + \mu_2 Y_2^* + \mu_3 Y_3^*) = \min \left\{ \frac{\mu_1}{\alpha_1}, \frac{\mu_2}{\alpha_2}, \frac{\mu_3}{\alpha_3} \right\} = \sigma_1, \]

which together with (18) and (13), imply (14). Using (15), one also easily obtains (17). \( \square \)

### 4 THE FINITENESS OF \( \mathcal{E}(p) \)

Following to Horn and Johnson,\textsuperscript{24} we recall some standard terminology. Given a quadratic matrix \( A \), we denote by \( A[\alpha, \beta] \) the submatrix of entries that lie in the rows of \( A \) indexed by \( \alpha \) and the columns indexed by \( \beta \). If \( \alpha = \beta \), the submatrix is called principal. The corresponding determinant \( \det A[\alpha, \alpha] \) is called the principal minor. An \( n \times n \) matrix has \( \binom{n}{k} \) distinct principal submatrices of size \( k \); i.e., totally, \( 2^n - 1 \) principal submatrices of order \( 1 \leq k \leq n \).

Since the left-hand side of (12) is a quadratic polynomial map in \( Y^* \), it follows from the standard algebraic geometry argument based on Bezout’s theorem that (12) has either (a) infinitely many or (b) at most \( 2^4 = 16 \) distinct solutions, counting the trivial point \( E_0 := 0 \). A simple analysis shows that under condition (9), (a) is not possible. Indeed, we have the following lemma, which can be justified by an elementary verification, but it has some several important implications.
Lemma 2. Let $A = (a_{ij})_{0 \leq i, j \leq 3}$ be the matrix in (6). Then, its determinant is
\[
det A = \Delta^2, \quad \Delta := \eta_1 \alpha_2 - \eta_2 \alpha_1, \tag{19}\]
and the only zero principal minors $\det A[\alpha, \alpha]$ are for
\[
\alpha \in \mathcal{G} := \{(0, 1, 2), (1, 2, 3), (1, 2), (1), (2), (3)\}.
\]

Let $\mathbb{R}^4(\alpha)$ denote the subset
\[
\mathbb{R}^4_+(\alpha) = \{x \in \mathbb{R}^4_+ : x_i = 0 \text{ for all } i \in \alpha\}.
\]
For instance, $\mathbb{R}^4(\emptyset) = \mathbb{R}^4_+$ and $\mathbb{R}^4_+(2, 3)$ are the face consisting of the point with coordinates $(x_1, 0, 0, x_4)$, where $x_1, x_4 \geq 0$.

Given a subset $\alpha \subset \{1, 2, 3, 4\}$, we denote by $\mathcal{E}(p, \alpha)$ the subset of $\mathcal{E}(p) \subset \mathbb{R}^4_+(\alpha)$, and by $\bar{\alpha}$, we denote the complement $\bar{\alpha} = \{1, 2, 3, 4\} \setminus \alpha$.

Here are some important observations following from Lemma 2.

Corollary 1. If $\alpha = \emptyset$, then $\mathcal{E}(p, \emptyset)$ consists of at most one point when $\Delta \neq 0$; if $\Delta = 0$, then $\mathcal{E}(p, \emptyset) = \emptyset$. In particular, the number of equilibrium points in the interior $\text{int}(\mathbb{R}^4_+)$ is at most one.

Proof. Indeed, the only nontrivial part here is the claim about the zero determinant (in this case, a priori maybe infinitely many solutions). To show that $\Delta = 0$ implies $\mathcal{E}(p, \emptyset) = \emptyset$, we assume by contradiction that there is some $Y \in \mathcal{E}(p, \emptyset)$. Setting $r := \eta_1 / a_1 = \eta_2 / a_2$, one readily obtains from the second and the third equations in $AY = q$ that $Y_0 - rY_3 = \frac{a_3}{a_1} = \frac{a_4}{a_2}$, which contradicts to (8).

Corollary 2. Card $(\mathcal{E}(p)) \leq 8$.

Proof. By Bezout’s theorem, we have card $(\mathcal{E}(p)) \leq 8$. Next, it is clear from (12) and Corollary 1 that for any admissible values of $p$ in (10), there can at most one equilibrium point exist in int $(\mathbb{R}^4_+)$. Any other equilibrium points must have zero coordinates. Next, since by Lemma 1 $Y_0^* \neq 0$ except $Y^* = 0$, at most $8 = 1 + 3 + 3 + 1$, distinct nonnegative equilibrium points may exist.

5 | BASIC FACTS ABOUT THE LINEAR COMPLEMENTARITY PROBLEM

An essential place in the further analysis plays the signs of $F_i(Y)$, where $Y$ is an equilibrium point of (4). In particular, the situation when all coordinates are nonpositive is very distinguished. We have the definition.

Definition 1. An equilibrium point $Y \in \mathcal{E}(p)$ of (4) is said to be $F$ stable if $F_i(Y) \leq 0$ for all $0 \leq i \leq 3$.

As we shall see below, if $p$ is admissible, then there always exists a unique $F$-stable point. To prove the existence and uniqueness, we employ the linear complementarity problem (LCP) machinery. An application of the LCP to Lotka-Volterra systems is not new and was firstly used by Takeuchi and Adachi; see also Takeuchi. On the other hand, in this paper, we are interested primarily in a finer structure of the $F$-stable points, namely, how this set depends on the fundamental parameters of the system. To proceed, we recall some basic facts about the linear complementarity problem.

The LCP consists of finding a vector in a finite dimensional real vector space that satisfies a certain system of inequalities. Specifically, given a vector $q \in \mathbb{R}^n$ and matrix $M \in \mathbb{R}^{n \times n}$, the LCP is to find a vector $z \in \mathbb{R}^n$ such that
\[
z \geq 0, \tag{20}
q + Mz \geq 0, \tag{21}
z^T(q + Mz) = 0. \tag{22}
\]

We refer to Cottle et al. for a comprehensive account of the modern development of LCP. Recall some standard terminology and facts following to Cottle et al. A vector $z$ satisfying the inequalities (20) and (21) is called feasible. Given a feasible vector $z$, let
\[
w = q + Mz.
\]
Then, $z$ satisfies (22) if and only if $z_i w_i = 0$ for all $i$. 
The correspondence between the general LCP and our model is given by virtue of (6) and (7) as follows:

\[ z \leftrightarrow Y^* \]
\[ w \leftrightarrow -F(Y^*) \]
\[ M \leftrightarrow -A \]
\[ q \leftrightarrow q. \]

(23)

Indeed, we are interested in nonnegative equilibrium points, i.e., in those solutions of (7), which satisfy

\[ Y_i \geq 0, \]

which is exactly condition (20). Furthermore, in this dictionary, (7) becomes equivalent to Equation 22. Finally, since by (5),

\[ q + Mz = q - AY = -F(Y) \geq 0, \]

i.e., condition (21) is equivalent to saying that the corresponding equilibrium point \( Y \) is \( F \)-stable.

In summary, we have

**Proposition 1.** \( Y \) solves the LCP \((-A, q)\) if and only if \( Y \) is an \( F \)-stable equilibrium point of (4).

The stability of (4) depends on the number of possible \( F \)-stable points of our model. In general, the structure of LCP \((A, q)\) may be very arbitrary. In some cases, depending on the matrix \( M \), however, one has a more strong information. Therefore, in order to study this question, we need to look at the matrix \( A \) in (6) more attentively. To this end, we make the following important remark: since

\[ A + A^T = \begin{pmatrix} -2b & 0 & 0 & 0 \\ 0 & K & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \]

it follows that \( A \) is negative semidefinite in the sense of quadratic forms. Then, it follows from the general LCP theory that the following existence result holds for positive definite matrices:

**Proposition 2.** (Theorem 3.1.6 in Cottle27). If a matrix \( M \) is positive definite, then the LCP \((q, M)\) has a unique solution for all \( q \in \mathbb{R}^n \).

In the next section, we shall apply a perturbation technique to utilize Proposition 2 to derive the existence of an \( F \)-stable point even for our semidefinite matrix \( A \). In order to prove the uniqueness, we shall also need the following well-known result, which proof we recall for the convenience reasons.

**Lemma 3.** Let \( M \) be positive semidefinite in the sense of quadratic forms. Then, the set of solutions of the LCP \((M, q)\) is convex.

**Proof of Lemma 3.** Let \( z \) and \( \bar{z} \) be any two solutions of LCP \((M, q)\) and let \( \zeta = az + b\bar{z} \), where \( 0 \leq a = 1 - b \leq 1 \). Then, (20) and (21) obviously hold for \( \zeta \). In order to verify (22), we note that \( z^Tw = \bar{z}^T\bar{w} = 0 \), where \( w = q + Mz \) and \( \bar{w} = q + M\bar{z} \). Hence,

\[ -\bar{z}^T\bar{w} - z^Tw = (z - \bar{z})^T(w - \bar{w}) = (z - \bar{z})^TM(z - \bar{z}) \geq 0. \]

Since \( \bar{z}^T\bar{w} \geq 0 \) and \( z^Tw \geq 0 \), we conclude that actually, the latter two inequalities are equalities; therefore,

\[ z^Tw = z^T\bar{w} = 0. \]

\[ \zeta^T(q + M\zeta) = (az + b\bar{z})^T(aw + b\bar{w}) \]
\[ = a^2z^Tw + b^2\bar{z}^T\bar{w} + ab(z^Tw + \bar{z}^T\bar{w}) \]
\[ = 0. \]

Hence, (22) holds true for \( \zeta \), and the lemma is proved.

# 6 THE EXISTENCE AND UNIQUENESS OF AN \( F \) STABLE POINT

We shall prove the main result (Theorem 1) of this section. The proof of existence and uniqueness of an \( F \)-stable point relies on the analysis of the associated LCP for a perturbed system (4). We make an essential use of a special structure of the matrix \( A \) in (6). Note, however, that for a general positive semidefinite matrix \( M \), the uniqueness of an \( F \)-stable point is failed.

**Theorem 1.** Let \( A \) be the matrix in (6) and let \( p \) be an admissible vector. Then, there exists a unique \( F \)-stable point of (4).
Proof. We consider a perturbation of (4). Let \( M = I\varepsilon - A \), where \( I \in \mathbb{R}^{4 \times 4} \) is the unit matrix. Then, \( M \) is positive definite for any \( \varepsilon > 0 \). Let \( z = z(\varepsilon) \) denote the unique solution accordingly to Proposition 2. Then, using the dictionary (23), we obtain

\[
z(\varepsilon) = (z_0(\varepsilon), z_1(\varepsilon), z_2(\varepsilon), z_3(\varepsilon)) \geq 0 \tag{24}
\]

\[
w(\varepsilon) := q + (I\varepsilon - A)z(\varepsilon) \geq 0 \tag{25}
\]

\[
w_i(\varepsilon)z_i(\varepsilon) = 0, \quad 0 \leq i \leq 3. \tag{26}
\]

Our first claim is that \( \max_{1 \leq i \leq 3} \{z_i(\varepsilon)\} \) is uniformly bounded when \( \varepsilon \to 0^+ \). We have

\[
0 = \sum_{i=0}^{3} w_i(\varepsilon)z_i(\varepsilon)
= \sum_{i=0}^{3} (q + (I\varepsilon - A)z_i(\varepsilon))z_i(\varepsilon)
= \frac{b}{K}z_0^2(\varepsilon) + \sum_{i=0}^{3} q_i z_i(\varepsilon) + \varepsilon z_i(\varepsilon)^2.
\]

Hence, we find from (6) that

\[
(b - \mu_0)z_0(\varepsilon) = \frac{b}{K}z_0^2(\varepsilon) + \sum_{i=1}^{3} \mu_i z_i(\varepsilon) + \varepsilon \sum_{i=0}^{3} z_i(\varepsilon)^2. \tag{27}
\]

Since the sums in the right-hand side are non-negative, we have \( (b - \mu_0)z_0(\varepsilon) \geq \frac{b}{K}z_0^2(\varepsilon) \); thus,

\[
z_0(\varepsilon) \leq \frac{K}{b}(b - \mu_0) = S_2, \tag{28}
\]

ie, \( z_0(\varepsilon) \) is uniformly bounded when \( \varepsilon \to 0^+ \). Using this in (27) yields

\[
\mu \max \{z_1(\varepsilon), z_2(\varepsilon), z_3(\varepsilon)\} \leq \sum_{i=1}^{3} \mu_i z_i(\varepsilon)
\leq \sum_{i=1}^{3} \mu_i z_i(\varepsilon) + \varepsilon \sum_{i=0}^{3} z_i(\varepsilon)^2 + \frac{b}{K}z_0^2(\varepsilon)
= (b - \mu_0)z_0(\varepsilon)
\leq (b - \mu_0)S_2,
\]

where \( \mu := \min \{\mu_1, \mu_2, \mu_3\} \). Therefore,

\[
\max \{z_1(\varepsilon), z_2(\varepsilon), z_3(\varepsilon)\} \leq \frac{(b - \mu_0)S_2}{\mu}. \tag{30}
\]

Hence, the first claim follows from (28) and (30).

Now, with the boundedness in hands, we conclude that there exists a sequence \( \varepsilon_j \to 0^+ \) such that \( z(\varepsilon_j) \) converges, say

\[
\lim_{\varepsilon \to 0^+} z(\varepsilon_j) = Y := (Y_0, Y_1, Y_2, Y_3).
\]

Then, for continuity reasons, we have

\[
Y \geq 0 \tag{31}
\]

\[
F(Y) = -q + AY \leq 0 \tag{32}
\]

\[
Y_iF_i(Y) = 0, \quad 0 \leq i \leq 3. \tag{33}
\]

Therefore, \( Y \) is an \( F \)-stable equilibrium point of (4).

Our next claim is that there thus obtained \( F \)-stable equilibrium point is unique. In order to prove this, note that by Lemma 3, the set of \( F \)-stable equilibrium points is convex. Suppose that \( Y \neq Y' \) are two \( F \)-stable equilibrium points of (4). Then, the segment between \( Y \) and \( Y' \) consists of \( F \)-stable equilibrium points. In other words, all points
\[ Y' = Y + vt, \] where \( 0 \leq t \leq 1 \) and \( v = Y - Y \) are \( F \)-stable equilibrium points. First, note that \( Y_0 = Y_0'. \) Indeed, applying (16) to \( Y' = Y + vt \) and differentiating twice the obtained identity with respect to \( t, \) we obtain \(-\frac{2b}{K}v_0 = 0; \) hence, \( v_0 = Y_0' = Y_0 = 0. \)

All other three coordinates of the segment are linear functions of \( t: Y'_i(t) := Y_i + (Y'_i - Y_i)t, 1 \leq i \leq 3; \) hence, they are either identically 0 or have at most one 0. Therefore, modifying, if needed the ends \( Y \) and \( Y', \) we may assume that for each \( i, \) exactly one condition holds (a) either \( Y'_i(t) \equiv 0 \) or (b) \( Y'_i(t) \neq 0 \) for all \( 0 \leq t \leq 1. \) Note also that at least one coordinate \( i \) must satisfy (a). Indeed, by the first claim of Corollary 1, the number of equilibrium points in the interior \( \text{int}(R^+) \) is at most one; therefore, for continuity reasons, none of \( Y \) and \( Y' \) can lie in \( \text{int}(R^+). \)

Thus, the above observations imply that \( Y \) and \( Y' \) must lie on the same face. Since by Lemma 1, \( Y_0 = Y_0' \neq 0, \) the face equation must be \( \{ Y_k = 0 : k \in K \} \) for some (nonempty!) subset \( K \subset \{ 1, 2, 3 \}. \) On the other hand, the non-zero coordinates \( Y'_i(t) \) must satisfy (15) and (16). Since the latter equations are linearly independent by (8) and the number of non-zero \( Y'_i(t) \) is \( \leq 3 - 1 = 2 \) (at least one must satisfy the condition (a)!), we conclude that there exists at most one solution. This contradicts to the infinitely many points in the segment between \( Y \) and \( Y' \) and thus finishes the proof of the uniqueness.

\[ \square \]

### 7 A FIner Structure of \( E(P) \)

In what follows, we are interested in the equilibrium points with non-negative coordinates only. According to Corollary 2, the set of equilibrium points is finite (there are at most eight distinct points in \( R^+ \)). Thus, to find which of these points is actually \( F \)-stable is the choice problem: it suffices to check that the corresponding \( F \)-coordinates are non-positive. Note that by Theorem 1, such a point must be unique. We make this analysis below.

Let \( p \) be an admissible parameter vector and let \( Y^* = Y^*(p) \) denote the unique \( F \)-stable equilibrium point of (4). It is easily to see that the trivial equilibrium \( 0 \) is never \( F \)-stable; i.e., the origin is the extinction equilibrium. Thus, by (13),

\[ 0 < Y^*_0 = Y^*_0(p) \leq S_2. \]

The identically zero coordinates of an equilibrium point is called its zero pattern. It follows from the structure properties of the matrix \( A \) that if \( p \) is admissible, then there can exist at most one point with a given zero pattern. A simple inspection yields the following nontrivial equilibrium points:

\[
\begin{align*}
E_2 &= (S_2, 0, 0, 0), \\
E_3 &= (S_3, (S_2 - S_3) \frac{b}{Ka_1}, 0, 0), \\
E_4 &= (S_4, 0, (S_2 - S_4) \frac{b}{Ka_2}, 0), \\
E_5 &= (S_5, 0, 0, (S_2 - S_5) \frac{b}{Ka_3}), \\
E_6 &= (S_6, (S_5 - S_6) \frac{a_3}{\eta_1}, 0, (S_6 - S_3) \frac{a_1}{\eta_1}), \\
E_7 &= (S_7, 0, (S_5 - S_7) \frac{\alpha_3}{\eta_2}, (S_7 - S_4) \frac{\alpha_2}{\eta_2}), \\
E_8 &= (S_8, (S_8 - S_7) \frac{b\eta_2}{K\Delta}, (S_6 - S_8) \frac{b\eta_1}{K\Delta}, (S_4 - S_3) \frac{\alpha_1\alpha_2}{\Delta}).
\end{align*}
\]

where

\[ \Delta = a_2\eta_1 - a_1\eta_2. \]

and \( S_k = S_k(p) := (E_k)_0 \) are the susceptible coordinates of the corresponding equilibrium state \( E_k \) given, respectively, by

\[
\begin{align*}
S_3 &= \sigma_1 < S_4 = \sigma_2 < S_5 = \sigma_3, \\
(S_2 - S_6) \frac{b}{Ka_1} &= (S_5 - S_3) \frac{\alpha_3}{\eta_1}, \\
(S_2 - S_7) \frac{b}{Ka_2} &= (S_5 - S_4) \frac{\alpha_1}{\eta_2}, \\
S_8 &= \frac{\Delta}{\Delta}, \quad \Delta := \mu_2\eta_1 - \mu_1\eta_2.
\end{align*}
\]
Note that modulo (35), the formulas (36) and (37) define explicitly $S_6$ and $S_7$, respectively. We also emphasize that $E_8$ exists (but maybe lie outside $E(p)$) if and only if $\Delta = \alpha_2 \eta_1 - \alpha_1 \eta_2 \neq 0$ (cf with Corollary 1).

The equilibrium point $E_2$ is the disease free equilibrium, while the remaining equilibria $E_k$, $k \geq 3$ are all endemic equilibria.

The above points $E_k$ (except for $E_8$) are well defined for all values of parameters; they can lie or not in $\mathbb{R}_+^4$, but only one of them is $F$ stable. The latter, however, must be understood in the sense that for certain values of parameter $p$, it may happen that two different notations $E_k$ coincide as points; for example, $E_3(p) = E_6(p)$. We discuss this in more details below in Section 9.

Remark 1. Note that by (9),

$$\Delta - \sigma_1 \Delta = (\sigma_2 - \sigma_1) \alpha_2 \eta_1 > 0,$$

in particular, $\Delta$ and $\Delta$ cannot vanish simultaneously.

Note also that the parameters $S_2, \ldots, S_8$ are dependent. On the other hand, we want to keep $S_2$ as a fundamental parameter of the model (the modified carrying capacity) and also consider $S_3, S_4$, and $S_5$ as the fundamental parameters satisfying the constraint (8). Then, it is convenient to think of $S_5, S_7$ and $S_8$ as depending on the first four fundamental parameters. It is worthy to mention also that one has from (36) and (37), the following additional relations:

$$\sigma_3 \Delta - \Delta = (S_5 - S_8) \Delta = (S_6 - S_7) \frac{b_1 \eta_2}{\alpha_5 K}, \quad (39)$$

$$\Delta - \sigma_1 \Delta = (S_8 - S_3) \Delta = (S_4 - S_5) \eta_1 \alpha_2, \quad (40)$$

$$\Delta - \sigma_2 \Delta = (S_8 - S_4) \Delta = (S_4 - S_5) \eta_2 \alpha_1. \quad (41)$$

Note that these formulas are well defined even if $E_8$ does not exist (ie, $\Delta = 0$). Note also that $S_8$ does not depend on $K$ and

$$S_8 = S_3 + \frac{(S_5 - S_3) \eta_1 \alpha_2}{\Delta} = S_4 + \frac{(S_4 - S_3) \eta_2 \alpha_1}{\Delta}. \quad (42)$$

To study the $F$ stability, we also write down the corresponding $F$ parts:

$$F(E_2) = (0, (S_2 - S_3) \alpha_1, (S_2 - S_4) \alpha_2, (S_2 - S_5) \alpha_3, 0),$$

$$F(E_3) = (0, 0, (S_3 - S_4) \alpha_2, (S_6 - S_3) \alpha_3 \frac{b_1 \eta_1}{K \alpha_1}, 0),$$

$$F(E_4) = (0, (S_4 - S_3) \alpha_1, 0, (S_7 - S_4) \alpha_3 \frac{b_2 \eta_3}{K \alpha_2}, 0),$$

$$F(E_5) = (0, (S_5 - S_6) \frac{b_1 \eta_1}{K \alpha_3}, (S_5 - S_7) \frac{b_2 \eta_3}{K \alpha_2}, 0, 0), \quad (43)$$

$$F(E_6) = (0, 0, (S_6 - S_8) \frac{\Delta}{\eta_1}, 0, 0),$$

$$F(E_7) = (0, (S_8 - S_7) \Delta \frac{\eta_1}{\eta_2}, 0, 0),$$

$$F(E_8) = (0, 0, 0, 0).$$

Using the obtained relation and the existence/uniqueness result, one may easily by inspection to find which of the seven points $E_i$ is $F$ stable for a given $p$. It is rather a trivial task for a concrete value of $p$, but of course, an explicit description of $k(p)$, where $E_{k(p)}$ is $F$ stable, is a more nontrivial problem. Still, it is possible to get some simple conditions to outline the main idea.

**Proposition 3.** The following $F$ stability conditions holds:

(a) the point $E_2$ is $F$ stable if and only if $S_2 \leq \sigma_1$, ie, when the carrying capacity is small enough;

(b) the point $E_3$ is $F$ stable if and only if $S_6 \leq \sigma_1 \leq S_2$;

(c) the point $E_5$ is $F$ stable if and only if

$$\sigma_3 \leq S_2;$$
(d) the point $E_6$ is $F$ stable if and only if
\[ (S_6 - S_8)\Delta \leq 0, \]
\[ \sigma_1 \leq S_6 \leq \sigma_3, \]
(e) the point $E_7$ is $F$ stable if and only if
\[ (S_8 - S_7)\Delta \leq 0, \]
\[ \sigma_2 \leq S_7 \leq \sigma_3, \]
(f) the point $E_8$ is $F$ stable if and only if
\[ \Delta > 0, \]
\[ \max\{0, S_7\} \leq S_8 \leq S_6. \]

In the borderline cases (when some inequality becomes an equality), the corresponding equilibrium points coincide; for example, if $S_2 = \sigma_1$, then $E_2 = E_3$.

**Proof.** First, it easily follows from (34) and (43) that $E_2 \geq 0$ always, while $F(E_2) \leq 0$ if and only if $S_i \geq S_2$ for all $i = 3, 4, 5$. By the uniqueness of an $F$-stable point, this immediately implies (coming back to the $\sigma$-notation in 35) that (a) holds. Similarly, $E_3 \geq 0$ if and only if $S_2 - S_3 \geq 0$, ie, $S_2 \geq \sigma_1$. On the other hand, since $(S_3 - S_4)\alpha_2 = (\sigma_1 - \sigma_2)\alpha_2 < 0$, we see that $F(E_3) \leq 0$ is equivalent to inequality $S_6 - S_3 \leq 0$, ie, $S_6 \leq \sigma_1$. This implies (b). Analysis of (c) to (e) is similar. Finally, analysis of $E_8$ reduces to the non-negativity of its coordinates. The last coordinate must be non-negative; hence (by virtue of $S_4 - S_3 = \sigma_2 - \sigma_1 > 0$), we must have $\Delta > 0$. This readily yields the desired inequalities.

We summarize the above observations to be some remarks. According to what was done before, we a priori know that the conditions of Proposition 3 are complementary to each other in the sense that they have no common (interior) points and give together the whole set of admissible parameters. This, however, is very difficult to see from the explicit defining inequalities. One reason for that is that the parameters $S_k, k = 6, 7, 8$ are dependent on the fundamental parameters. Also, it is not a priori clear that any of the conditions in Proposition 3 is realizable for some $p$. In fact, it is an elementary exercise to verify that any of the $E_k, k \in \{2, 3, 5, 6, 7, 8\}$ may be realizable for some admissible $p$. The reader can easily verify this by expanding the explicit values for $S_k, k = 6, 7, 8$ in the above inequalities, but we do not give these rather cumbersome expressions. Instead, a more important question is to study the dependence of the $F$-stable point on some distinguished parameters like the carrying capacity $K$. We consider this problem in more details below in Section 9.

Finally, as for many epidemiology models, the above results could also be interpreted as the threshold in terms of the basic reproduction number $R_0$, which is usually defined as the average number of secondary infections produced when one infected individual is introduced into a host population where everyone is susceptible. In the context of the present paper, the most natural definition of the basic reproduction number for a virus would be similar to that considered by Allet et al. It follows also that there are additional threshold values, which depend on the dynamics of the population size at the equilibrium values; see the discussion, cf Allen et al. p. 198

**8 | THE GLOBAL STABILITY**

Now, connect the concept of the $F$ stability to the Lyapunov stability. Recall that an equilibrium point $Y^* = (Y^*_0, Y^*_1, Y^*_2, Y^*_3) \in \mathcal{E}(p)$ is called $F$ stable if $Y^*_i \geq 0$ and $F_i(Y^*) \leq 0$ for any $0 \leq i \leq 3.29,30$ An $F$-stable point $Y^*$ is said to be degenerate if $Y^*_i = F_i(Y^*) = 0$ for some $0 \leq i \leq 3$. In other words, an equilibrium point $Y^*$ is degenerate if the total number of non-zero coordinates of both $Y^*$ and $F(Y^*)$ is less than 4.

The above terminology can be motivated by the following observation. Given $Y^* \in \mathcal{E}(p)$, we associate the generalized Volterra function
\[ V_{Y^*}(y_0, y_1, y_2, y_3) = \sum_{i=0}^{3} (y_i - Y^*_i \ln y_i). \]

Then, the time derivative of $V_{Y^*}$ along any integral trajectory of (4) is given by
\[ \frac{d}{dt} V_{Y^*} := (\nabla V_{Y^*})^T \frac{dy}{dt} = - \frac{b}{K} (y_0 - Y^*_0)^2 + \sum_{i=0}^{3} F_i(Y^*)y_i. \]
Therefore, if \( Y^* \) is an \( F \)-stable point of (4), then it is Lyapunov stable:

\[
\frac{d}{dt} V_{Y^*}(y(t)) \leq 0.
\]

(45)

The following elementary observation is a useful tool to sort away certain \( F \)-stable points.

**Proposition 4.** The equilibrium points \( E_1 = 0 \) and \( E_4 \) are never \( F \) stable.

*Proof.* Indeed, \( F(E_1) = b - \mu_0 > 0 \) and \( F(E_4) = \alpha_1(\sigma_2 - \sigma_1) > 0 \).

Our principal result establishes the existence and uniqueness of an \( F \)-stable point.

**Theorem 2.** The \( F \)-stable point \( Y^*(p) \) is globally stable; i.e., \( Y(t) \to Y^*(p) \) as \( t \to \infty \) for any solution of (1) with initial data (3). Furthermore,

\[
0 < \min\{S_2, \sigma_1\} \leq Y^*_0(p) \leq \min\{S_2, \sigma_3\}.
\]

In particular, \( Y^*_0(p) \leq \sigma_3 \) with the equality if and only if \( Y^*(p) = E_5 \).

**Remark 2.** Note, however, that an explicit representation and the zero pattern of the corresponding \( F \)-stable point \( Y^*(p) \) depend in a tricky way on the fundamental parameter \( p \). The proof of the global stability makes an essential use of the fact that \( Y_0(t) \) has a non-zero limit value. This allows us to obtain nontrivial first integrals, which reduce the dimension of the \( \omega \)-limit set to 0.

**Remark 3.** The asymptotic behaviour of (1) maybe, however, rather complex if \( K = \infty \) and will be treated somewhere else. Note also that if \( K = \infty \), the system (1) is no longer semidefinite but it has the pure skew symmetric structure instead. More precisely, the matrix \( A \) in (6) is skew symmetric and can be thought of as a perturbation of the decomposable matrix

\[
B = \begin{pmatrix}
0 & -\sigma_1 & 0 & 0 \\
\sigma_1 & 0 & 0 & 0 \\
0 & 0 & 0 & -\eta_2 \\
0 & 0 & \eta_2 & 0
\end{pmatrix}.
\]

The dynamic of perturbed Lotka-Volterra systems obtained by perturbation of \( B \) can be very complex and contain nontrivial attractors in \( \mathbb{R}^4 \), as the recent results of Duarte et al.\( ^{32} \) Part II show.

We begin by proving some auxiliary statements.

**Proposition 5.** If \( Y(t) \) is a solution of (4) satisfying (3), then

\[
Y_0(t) \leq \left( \frac{1}{S_2} \left( 1 - e^{-(b - \mu_0)t} \right) + \frac{1}{Y_0(0)} e^{-(b - \mu_0)t} \right)^{-1}.
\]

(46)

In particular,

\[
Y_0(t) \leq \max\{S_2, Y_0(0)\},
\]

(47)

and

\[
\limsup_{t \to \infty} Y_0(t) \leq S_2.
\]

(48)

*Proof.* It follows from the first equation of (4) that

\[
Y'_0 - (b - \mu_0)Y_0 \leq -\frac{bY_0^2}{K},
\]

which can be written as

\[
(Y_0 e^{-(b - \mu_0)t})' \leq -\frac{b}{K} e^{-(b - \mu_0)t} Y_0^2.
\]
Integrating the latter inequality gives
\[ \frac{e^{b-\mu_0 t}}{Y_0} \geq \frac{b}{K(b-\mu_0)} (e^{b-\mu_0 t} - 1) + \frac{1}{Y_0(0)}, \]
which proves (46). Relations (47) and (48) are direct consequences of (46).

**Proposition 6.** If \( Y(t) \) is a solution of (4) with (3), then
\[ \sum_{i=0}^{3} Y_i(t) \leq \max \{ \sum_{i=0}^{3} Y_i(0), \frac{Kb}{4\hat{\mu}} \}, \]
for \( t \geq 0 \), where \( \hat{\mu} := \min \{ \mu_0, \mu_1, \mu_2, \mu_3 \} \). In particular, any solution of (4) with initial data (3) is bounded.

**Proof.** Summing up all equations of (4) gives
\[ \frac{d}{dt} \sum_{i=0}^{3} Y_i(t) = \frac{b}{K}(S_2 - Y_0)Y_0 - \sum_{i=1}^{3} \mu_i Y_i(t) \leq \frac{b}{K}(K - Y_0)Y_0 - \hat{\mu} \sum_{i=0}^{3} Y_i(t). \]
Setting \( f(t) = \sum_{i=0}^{3} Y_i(t) \), we find \( f'(t) \leq \frac{bK}{4} - \hat{\mu} f(t) \). By integrating the above equation, we obtain the desired inequality. \( \square \)

**Proof of Theorem 2.** According to Theorem 1, there exists a unique \( F \)-stable point; we denote it by \( Y^* \). Let \( Y(t) \) be any solution of (4) with initial conditions (3). First note that by (44), the Volterra function \( V_{Y^*}(t) \) is non-increasing for all \( t \geq 0 \); therefore,
\[ V_{Y^*}(Y(t)) \leq V_{Y^*}(0). \]

On the other hand, \( V_{Y^*}(t) \) is a priori bounded from below. Indeed, it is easily verified that the function of one variable \( \psi_a(x) = x - a \ln x \) is decreasing in \((0, a)\) and increasing for \( x \in (a, \infty) \); thus,
\[ \psi_0(x) = x - a \ln x \geq \psi_a(a) = a - a \ln a, \quad x \in (0, \infty), \]
(where the above inequality also holds in the limit case \( a = 0 \)). It follows that
\[ V_{Y^*}(Y) \geq V_{Y^*}(Y^*), \]
and the equality holds if and only if \( y = Y^* \). Thus, \( V_{Y^*}(Y(t)) \) is uniformly bounded in \( \mathbb{R}_+^+ \). Coming back to (44), note that by our choice of \( Y^* \), all \( F_i(Y^*) \leq 0 \) and also \( Y_i \geq 0 \); therefore, for any \( T > 0 \),
\[ \int_0^T \frac{b}{K}(Y_0(t) - Y_0^*)^2 dt + \sum_{i=0}^{3} \left| F_i(Y^*) \right| \int_0^T |Y_i(t)| dt = V_{Y^*}(Y(0)) - V_{Y^*}(Y(T)). \]
This immediately implies by the uniform boundedness of \( V_{Y^*}(Y(t)) \) that
\[ \text{for any } 0 \leq i \leq 3, \text{ all derivatives } Y_i'(t), Y_i''(t), \ldots, Y_i^{(k)}(t), \text{ of any order } k \geq 1 \text{ are uniformly bounded in } [0, \infty). \]

Combining (52) and (a) with Lemma 5 in Appendix A, we conclude that the following limit exists:
\[ \lim_{t \to \infty} Y_0(t) = Y_0^*. \]
Recall also that since \( Y_0^* \neq 0 \), then
\[ F_0(Y^*) = 0. \]
Next, let $I$ denote the subset of $\{1, 2, 3\}$ such that $F_i(Y^*) \neq 0$ for some $i \in I$. Then, by (12), $Y_i^* = 0$, and on the other hand, by (b), we have $Y_i(t) \in L^1([0, \infty))$. Applying Lemma 4, we find
\[
\lim_{t \to \infty} Y_i(t) = 0 = Y_i^*, \quad i \in I.
\] (55)

It remains to establish that $Y_j(t)$ converges also for $j \in J = \{1, 2, 3\} \setminus I$. Alternatively,
\[
J = \{ j \geq 1 : F_j(Y^*) = 0 \}.
\]

Arguing as above and combining (52) with Corollary 3, we obtain
\[
\lim_{t \to \infty} \frac{d^k}{dt^k} Y_0(t) = 0 \quad \text{for any } k = 0, 1, 2, \ldots.
\] (56)

We have by (56) that
\[
\lim_{t \to \infty} \frac{d}{dt} Y_0(t) = \lim_{t \to \infty} Y_0(t) F_0(Y(t)) = 0.
\] (57)

Since $\lim_{t \to \infty} Y_0(t) = Y_0^* \neq 0$, we obtain that
\[
\lim_{t \to \infty} Y_0(t) F_0(Y(t)) = 0.
\] (58)

Hence,
\[
\lim_{t \to \infty} \sum_{i=1}^{3} a_i Y_i(t) = \frac{b}{K}(S_2 - Y_0^*).
\] (59)

Since we also know that (55) holds true for any $i \in I$, we may simplify (59) to obtain
\[
\lim_{t \to \infty} \sum_{j \in J} a_j Y_j(t) = \frac{b}{K}(S_2 - Y_0^*).
\] (60)

On the other hand, since $V_{Y^*-}(Y(t))$ is non-increasing and bounded, we similarly obtain
\[
\lim_{t \to \infty} \sum_{j \in J} (Y_j(t) - Y_j^* \ln Y_j(t)) = C,
\] (61)

where $C$ is some real constant.

To proceed, we iterate (56) by virtue of (4). For example, the second derivative is obtained by
\[
\frac{d^2}{dt^2} Y_0(t) = \frac{d}{dt} (Y_0(t) F_0(Y(t))) = Y_0' F_0(Y) + Y_0 \sum_{l=0}^{3} \frac{\partial F_0}{\partial Y_l} Y_l'(t)
\]
\[
= Y_0 \left( F_0^2(Y) + \sum_{l=0}^{3} Y_l F_l \frac{\partial F_0}{\partial Y_l} \right) = Y_0 \mathcal{L}(F_0),
\]

where $\mathcal{L}$ is a Riccati-type operator $\mathcal{L}(g) = g^2 + \sum_{l=0}^{3} Y_l F_l \frac{\partial g}{\partial Y_l}$. Then, (56) and (53) imply that
\[
\lim_{t \to \infty} \mathcal{L}^k(F_0)(Y(t)) = 0, \quad \text{for all } k = 0, 1, 2, \ldots.
\]

For example, $k = 1$ yields by virtue of (53), (55), (54), and (58) that
\[
\lim_{t \to \infty} \sum_{j \in J} a_j Y_j(t) F_j(Y(t)) = 0.
\] (62)

Next, note that if the cardinality of $J$ is exactly one, then the left-hand side of (60) contains only one term, thus implying the convergence of the corresponding $J$-coordinate. Therefore, we may assume without loss of generality that $J$ contains at least two indices.

We consider the two cases.
Case 1. Let $J$ be maximal possible; ie, $J = \{1, 2, 3\}$. Then, it must be

$$F(Y^*) = (0, 0, 0, 0).$$

We have from (59), (53), (62), (61), and explicit expressions for $F$, that

$$\lim_{t \to \infty} G(Y(t)) = \frac{b}{K}(S_2 - Y_0^*),$$

$$\quad$$

$$\lim_{t \to \infty} H(Y(t)) = 0,$$

$$\lim_{t \to \infty} V_Y(Y(t)) = C,$$

where $G(y) = \sum_{i=1}^{3} a_i y_i$, $H(y) = \sum_{i=1}^{3} a_i c_i y_i + y_1 y_3(\alpha_3 - \alpha_1) \eta_1 + y_2 y_3(\alpha_3 - \alpha_2) \eta_2$, and $c_i = a_i(Y_0^* - \sigma_i)$. Then, (63) to (65) imply that the $\omega$-set of the trajectory $Y(t)$ is a subset of the variety defined by

$$G(y_1, y_2, y_3) = \frac{b}{K}(S_2 - Y_0^*),$$

$$H(y_1, y_2, y_3) = 0,$$

$$V_Y(y_1, y_2, y_3) = C.$$}

We claim that the latter system has only finitely many solutions in $\mathbb{R}^3$. Indeed, the left-hand sides of (63) and (64) are algebraic polynomials of degree 1 and at most 2, respectively. Therefore, (63) and (64) define either a curve of order two or a line or a plane. The latter is, however, possible only if the linear form $\phi := \sum_{i=1}^{3} a_i y_i - \frac{b}{K}(S_2 - Y_0^*)$ divides $H$. Let us show that the latter is impossible. Indeed, suppose that $\phi$ divides $H$, then must exist a linear function $P$ of $y$ such that

$$\sum_{i=1}^{3} a_i c_i y_i + y_1 y_3(\alpha_3 - \alpha_1) \eta_1 + y_2 y_3(\alpha_3 - \alpha_2) \eta_2 = \left(\sum_{i=1}^{3} a_i y_i - \frac{b}{K}(S_2 - Y_0^*)\right)P.$$

On substitution $y_1 = y_2 = 0$ into the latter identity we obtain

$$a_3 c_3 y_3 = (a_3 y_3 - \frac{b}{K}(S_2 - Y_0^*))P(0, 0, y_3).$$

Therefore, $S_2 = Y_0^*$. But we know by Lemma 1 that the latter holds if and only if $Y^* = E_2 = (S_2, 0, 0, 0)$ in which case, we have

$$F(Y^*) = F(E_2) = (0, (S_2 - \sigma_1)a_1, (S_2 - \sigma_2)a_2, (S_2 - \sigma_3)a_3).$$

see (43). But by (9), there exist at least two non-zero coordinates in $F(Y^*)$, a contradiction with the initial assumption. This proves that (63) and (64) define either a curve of order two or a straight line. Next, since at least one of $Y_i^*$ is non-zero for $i \geq 1$ (because $Y^* \neq E_2$), it follows that Equation (68) is transcendent (contains a logarithm). A simple argument shows that in that case, (63) to (65) must have at most finitely many (more precisely, $\leq 6$) solutions. Thus, the $\omega$-set is finite, implying for continuity reasons that the $\omega$-set is a point; ie, all three limits, $\lim_{t \to \infty} Y_i(t), 1 \leq i \leq 3$, must exist. Then, a standard argument reveals that the only possibility here is that the limit point is $Y^*$.

Case 2. It remains to consider the case when the cardinality is exactly two; ie, $J$ is obtained by eliminating some index $i \in \{1, 2, 3\}$. Write this as $J = \{j, k\}$ such that $\{1, 2, 3\} = \{i, j, k\}$. By the made assumption, $F_i(Y^*) \neq 0$, $\lim_{t \to \infty} Y_i(t) = 0 = Y_j^*$, and

$$F_j(Y^*) = F_k(Y^*) = 0.$$

Again, eliminating the trivial case $Y^* = E_2$, we may assume that at least one of coordinates, say $Y_j^*$, is non-zero. This implies that $V_{Y_j}(y_j, y_k)$ is a transcendent function. Repeating the argument in Case 1, we again arrive to the finiteness of the $\omega$-set, implying the convergence of $Y(t)$ to $Y^*$. The theorem is proved completely.
9 | TRANSITION DYNAMICS OF AN F STABLE POINT

From the biological point of view, it is important to know how the dynamics of the $F$-stable equilibrium point $Y^*(p)$ depends on the fundamental parameter $p \in \mathbb{R}^3$. We have the following general result.

**Theorem 3.** The map $p \to Y^*(p)$ is continuous for any admissible $p$. Furthermore, for any continuous perturbation of the fundamental parameter $p$ (keeping $p$ admissible), the $F$-stable nondegenerate point $Y^*(p) = E_k(p)$ may change its index $k(p)$ only along the edges of the graph $\Gamma$ drawn in Figure 2.

**Proof.** First note that an $F$-stable point is uniquely determined as the (unique) solution $Y^*(p)$ of the system

$$
Y^*(p) \geq 0,
F(p, Y^*(p)) \leq 0,
Y_i^*(p)F_i(p, Y^*(p)) = 0, \quad \forall i = 0, 1, 2, 3,
$$

where $F_i(p, Y)$ are obtained from (6). Let $p_k \to p_0$ be a sequence of admissible points converging to an admissible value $p_0$. Then, each $Y^*(p_k)$ satisfies (69) for $p = p_k$. It also follows from (17) that $Y^*(p_k)$ is a bounded subset of $\mathbb{R}_+^4$, thus has an accumulation point, say $\lim_{k \to \infty} Y^*(p_k) = \tilde{Y}$ for some subsequence $k_i \to \infty$. Since the left-hand sides of (69) are continuous functions, $\tilde{Y}$ satisfies (69) for $p = p_0$; therefore, by the uniqueness, $\tilde{Y} = Y^*(p_0)$. This also implies that there can exist at most one accumulation point of $\{Y^*(p_k)\}_{k \geq 1}$; therefore, $Y^*(p_k)$ must converge to $Y^*(p_0)$; the continuity of $p \to Y^*(p)$ follows.

In particular, it is important to describe the dependence $K \to Y^*(K)$ when all other parameters

$$
q = (\mu_i, a_j, \eta_k) \in \mathbb{R}_+^8, \quad 1 \leq i \leq 3, 1 \leq j \leq 3, 1 \leq k \leq 2,
$$

are fixed and admissible (ie, 9 is satisfied). A closer inspection of (14) and (34) reveals the following monotonicity result.

**Theorem 4.** The susceptible class $Y_0^*(p)$ is a nondecreasing function of $K$. More precisely, $Y_0^*(p)$ is locally strongly monotonic increasing if $Y^*(p) = E_k$ with $k \in \{2, 6, 7\}$, and it is locally constant if $Y^*(p) = E_5$ with $k \in \{3, 5, 8\}$.

According to Theorem 4, there can exist only three following transition scenarios (depending on the choice of $q \in \mathbb{R}_+^8$). Namely, if $K$ is increasing in $(0, \infty)$, then exactly, one of the following alternatives holds

(a) $E_2 \to E_3$;
(b) $E_2 \to E_3 \to E_6 \to E_5$ (if $S_8 \geq \sigma_3$);
(b') $E_2 \to E_3 \to E_6 \to E_8$;
(c) $E_2 \to E_4 \to E_6 \to E_8 \to E_7 \to E_5$.

Note also that it follows from (c) in Proposition 3 that if $E_3$ is $F$ stable for some value of $S_2$, then it remains $F$ stable for the larger values. In other words, if for some $K_0$, the system equilibrium bifurcates to $E_5$, then it remains there for all $K \geq K_0$.

The corresponding graphs of the susceptible class $Y_0^*(p)$ are pictured in Figure 3. Recall that the modified carrying capacity $S_2 = K(1 - \frac{p_0}{b})$ is proportional to $K$.

We emphasize the monotonic nondecreasing dependence of $Y_0^*(p)$ as a function of $K$. It is also interesting to point out that the value of $Y_0^*(p)$ stabilizes when $K \geq K^*(q)$. In other words, after a certain threshold value $K^*(q)$, the equilibrium point $Y^*(K, q)$ still depends on $K$ except for the susceptible class, which becomes constant.

Let $p$ be a fixed admissible vector. Then, it easily follows from (34) and (43) that if $0 < S_2 < \sigma_1$, then $Y^*(p) = E_2$ is the $F$-stable point. If $S_2 = \sigma_1$, then $E_2 = E_3$ is the $F$-stable point. Similarly, using (36), we also see that if

$$
\sigma_1 < S_2 < \sigma_1' := \sigma_1 + (\sigma_3 - \sigma_1) \frac{K \alpha_1 \alpha_3}{b \eta_1},
$$

then $E_2 \to E_3 \to E_6 \to E_5$.

**FIGURE 2** The transition graph $\Gamma$ of $F$-stable points as a function of the carrying capacity $K$. If $S_8 \geq \sigma_3$, then $E_3, E_7$ are absent.
then $Y^*(p) = E_3$. When $S_2 = \sigma_1'$, we have $\sigma_1 = S_3 = S_6$, and it follows from (36) that in fact, $Y^*(p) = E_3 = E_6$. If $S_2$ becomes a bit large than $\sigma_1'$, then $Y^*(p) = E_6$. By (d) of Proposition 3, we have that $E_6$ is $F$ stable if and only if $(S_6 - S_8)\Delta \leq 0$ and $\sigma_1 \leq S_6 \leq \sigma_3$. First, let $\Delta > 0$. Since by (42), $S_8 > \sigma_2 = S_4$, and by (36), $S_6$, are an increasing function of $K$, $E_6$ will be $F$ stable exactly when $S_6$ increases between $\sigma_1$ and $\min \{\sigma_3, S_8\}$. If (a) $\sigma_3 < S_8$, then since $S_6$ is given by (42), for $S_6 = \sigma_3$, the point $E_6$ bifurcates in $E_5$. If (b) $\sigma_3 \geq S_8$, $E_6$ bifurcates in $E_6$. Now, let $\Delta < 0$. Then, (42) implies $\sigma_1 > S_6$; hence, $(S_6 - S_8)\Delta < 0$ if $S_6 \geq \sigma_1$. Therefore, the $F$ stability of $E_6$ is equivalent to a single condition $\sigma_1 \leq S_6 \leq \sigma_3$; thus, we are in position (b), and $E_6$ is stable for all $\sigma_1 \geq S_6 \leq \sigma_3$, and then, $E_6$ bifurcates in $E_8$ when $S_6 = \sigma_3$.

Let us consider as an example the behaviour of the equilibrium point $Y^*(p) = E_5$. Suppose that $Y^*(p) = E_5$ is $F$ stable for some $p$ but it is a degenerate point. Since $(E_5)_b$ and $(E_5)_3$ are positive, the degeneracy means that, for instance, $(F(E_5))_1 = 0$. This yields $S_5 = S_6$. We claim that in that case, $E_5 = E_6$. Indeed, one trivially has $(E_5)_b = S_5 = S_6 = (E_6)_b$ and $(E_5)_3 = 0 = (E_6)_3$ for $i = 1, 2$. Also, using (36), we get

$$(E_5)_3 = (S_2 - S_3)\frac{b}{K\alpha_3} = (S_2 - S_6)\frac{b}{K\alpha_3} = (S_5 - S_3)\frac{a_1}{\eta_1} = (S_6 - S_3)\frac{a_1}{\eta_1} = (E_6)_3.$$ 

Thus, $Y^*(p) = E_5 = E_6$. In particular, $(F(E_6))_2 = (F(E_5))_2 \leq 0$. If the latter inequality is strong, then $Y^*(p) = E_6$; hence, $Y^*(p)$ is nondegenerate. If $(F(E_5))_2 = 0$, then $S_5 = S_6 = S_7$, which imply by the same argument that $E_5 = E_6 = E_7$. Then, it follows from (39) that $\sigma_3\Delta = \Delta$. Using Remark 1, $\Delta$ and $\Delta$ are non-zero; therefore, $S_6 = \frac{\Delta}{\Delta} = \sigma_3 = S_5$. In particular, this yields from (40) that $(\sigma_3 - \sigma_1)\Delta = (\sigma_2 - \sigma_1)\eta_1\alpha_2$; hence, $\Delta > 0$. It follows that $E_8 = E_5$. But the latter (since $E_6$ missing the $F$-components) means that $Y^*(p) = E_5$ is nondegenerate.

In general, using the above argument implies that if $E_k$ is $F$ stable but degenerates, then there exists $F$ stable and non-degenerate $E_m$ with $m > k$ such that $E_m = E_k$. It interesting to understand the corresponding transition dynamics. To this end, let us write $(i,j) \in E_k$ (respectively, $\in F(E_k)$ if $c(S_i - S_j)$ is present in $E_k$ (respectively, $F(E_k)$). If $(i,j) \in E_k$ (or $F(E_k)$) implies that either $i = k$ or $j = k$ (this holds even true for $E_k$ modulus relations 40 or 41). A simple examination shows that the following subordination principle holds true.

**Proposition 7.** $(i,j) \in E_i$ if and only if $(i,j) \in F(E_i)$ and if $(i,j) \in E_j$ (respectively, in $F(E_j)$) then $i < j$ (respectively, $i > j$).

Let us denote by $E = \{(i,j) : \text{there exists } E_i \text{ such that } (i,j) \in E_i \}$ and let $\Gamma$ denote the undirected graph with nodes \([k : 2 \leq k \leq 8]\) and edges $E$; see Figure 2. From the biological point of view, the graph $\Gamma$ shows the transition dynamics of a $F$-stable point $Y^*(p)$ depending on continuous perturbations of $p$. 

**FIGURE 3** The possible scenarios of the transition dynamics 

---

A. B. C. D.
The trivial equilibrium $E_1 = 0$ (i.e., when no disease or susceptible), the disease-free equilibrium point $E_2$, the equilibrium states with the presence of first and second strain and the presence of coinfections $E_3, E_4, E_5$ and the equilibrium states corresponding the coexistence of more than two classes $E_6, E_7, E_8$.

### 10 Some Remarks on the Infinite Carrying Capacity

To complete the above picture, we announce without proofs some results on the case of very high (infinite) carrying capacity, i.e., $K = \infty$. We return to this situation with detailed discussion somewhere else. The dynamics of the limit case $K = \infty$ are completely different, and the global stability is failed in this case; see Remark 3. Still, we have some nice properties that hold for general parameters.

An easy analysis shows that for $K = \infty$, some equilibrium points from (34) disappear (“pass to infinity”), so that, generically, only following three equilibrium points exist:

$$
E'_3 = \left( \sigma_1, \frac{b - \mu_0}{\alpha_1}, 0, 0 \right),
$$

$$
E'_5 = \left( \sigma_3, 0, 0, \frac{b - \mu_0}{\alpha_3} \right),
$$

$$
E'_8 = \left( \frac{\Delta}{\Delta}, \frac{\gamma_2}{\Delta}, \frac{\gamma_1}{\Delta}, (\sigma_2 - \sigma_1) \frac{\alpha_1 \alpha_2}{\Delta} \right),
$$

where we assume that

$$
\gamma_1 = \eta_1 (b - \mu_0) - \alpha_1 \alpha_3 (\sigma_3 - \sigma_1),
$$

and

$$
\gamma_2 = \alpha_2 \alpha_3 (\sigma_3 - \sigma_2) - \eta_2 (b - \mu_0),
$$

are non-zero quantities. The corresponding nontrivial $F$-parts are

$$
F(E_3) = \left( 0, 0, (\sigma_1 - \sigma_2) \frac{\alpha_1 \alpha_3}{\alpha_1}, \frac{\gamma_1 \alpha_3}{\alpha_1} \right),
$$

$$
F(E_5) = \left( 0, -\frac{\gamma_1}{\alpha_3}, \frac{\gamma_2}{\alpha_3}, 0 \right).
$$

In the borderline case $\gamma_1 \gamma_2 = 0$, analysis is somewhat more delicate; here, there exist two points that correspond to $E_6$ and $E_7$ for $K < \infty$.

![Figure 4](image-url)  
**Figure 4** Three equilibrium states for $K = \infty$ (the point $P$ is given by $\gamma_1 = \gamma_2 = 0$)
Then, the stability diagram is shown in Figure 4.

**Proposition 8.** Suppose that $K = \infty$ holds. Then, for any $q \in \mathbb{R}^4$, such that $\gamma_i \neq 0$, $i = 1, 2$, there exists a unique $F$-stable point $Y^*(p) \in \{E'_3, E'_5, E'_8\}$; see Figure 4. Moreover, in each of the three cases, the $\omega$-limit set $\omega(Y)$ of a solution to (1) is one of the following:

- **a.** If $Y^*(p) = E'_3$, then $\omega(Y) = \{y \in \mathbb{R}^4 : y_2 = y_3 = 0, \ y_0 - Y_0^* \ln y_0 + y_1 - Y_1^* \ln y_1 = C_1\}$,
- **b.** If $Y^*(p) = E'_5$, then $\omega(Y) = \{y \in \mathbb{R}^4 : y_1 = y_2 = 0, \ y_0 - Y_0^* \ln y_0 + y_3 - Y_3^* \ln y_1 = C_2\}$,
- **c.** If $Y^*(p) = E'_8$, then $\omega(Y) = \{y \in \mathbb{R}^4 : y_0 - Y_0^* \ln y_0 + y_1 - Y_1^* \ln y_1 + y_2 - Y_2^* \ln y_2 + y_3 - Y_3^* \ln y_3 = C_3\}$,

where $C_i$ are some constants.

Thus, the $\omega$-limit sets are either one-dimensional curves in the first two cases or a compact hypersurface in $\mathbb{R}^4$ otherwise.

11 | DISCUSSION

In this paper, we proposed an SIR model with coinfection-infection mechanism and observed the effect of density dependence population regulation on disease dynamics. The complete stability analysis of boundary equilibrium points and coexistence equilibrium point revealed that there is always a unique $F$-stable equilibrium point for any admissible set of parameters. The existence of an endemic equilibrium point guarantees the persistence of the disease with a possible future threat of any outbreak in the population. In the absence of dual infection, exclusion of a strain with an invading strain was also observed, which proves the existence of competitive exclusion principle. Furthermore, we have also shown that addition of a density dependence factor in the susceptible population has played an important role in the disease dynamics. Increase in carrying capacity increases the number of $F$-stable equilibrium points, which makes the dynamics even more complicated. If carrying capacity is significantly high, then the oscillation in different classes is observed, and these oscillations dampen to equilibrium point, but it approaches the equilibrium point very slowly. We also find that increasing the resources of the population, increased carrying capacity, for example, by increased wealth, can increase the risk of infection, which leads to a destabilization of a healthy population. This becomes especially interesting in the limit case when carrying capacity is very large. Then, the healthy population is independent of carrying capacity (increased wealth), since the susceptible population remains constant for very large $K$. Instead, the infected population increase as it depends on carrying capacity yet may reach a limit for infinitely large carrying capacities. An increased wealth may therefore only fuel the number of infected in the population, which is very different from general expectations. These dynamics resemble the top-down regulation in food chains and food webs.33 In the limit case, when $K = \infty$, we have observed the periodic behaviour of solution trajectories in the limit, which becomes even more complex for coexistence equilibrium point. These results indicate that this system has dynamics closely related to the Rosenzweigs34 who cite famous paradox of enrichment for predator prey models and Sharp and Pastor21 have also found the paradox for a disease model. In the future, we would also like to see if it is possible to analyse this model with more complexity by adding the interaction between two strains and to conduct the global stability analysis for that extended model.

REFERENCES

APPENDIX A: TWO AUXILIARY LEMMAS

The following results are in the spirit of the well-known Landau-Kolmogorov-type estimates. On the other hand, our focus is non on an inequality but on the convergence at infinity. We were unable to find any explicit formulations like the lemmas below. On the other hand, these results are interesting by their own right and are very useful tools in integral estimates of a rather general ODEs including those of Lotka-Volterra type.

Lemma 4. If \( f(t) \in L^p([0, \infty)) \cap C^1([0, \infty)) \), where \( p \geq 1 \) and \( f' \in L^\infty([0, \infty)) \), then there exists \( \lim_{t \to \infty} f(t) = 0 \).

Proof. Let \( M = \| f' \|_{L^\infty([0, \infty))} \). Arguing by contradiction, we can suppose that there exists \( t_k \not\to \infty \) such that \( t_k+1 - t_k > \frac{\Delta}{M} \) and \( |f(t_k)| \geq \Delta \), for some fixed \( \Delta > 0 \). Since the first derivative is bounded: \( |f'(t)| \leq M \) for all \( t \geq 0 \), we have by the mean value theorem for any \( t, t_k \leq t \leq t_k + \frac{\Delta}{M} \),

\[
    f(t) = f(t_k) + f'(\xi)(t-t_k) \\
    \geq \Delta - M(t-t_k) \\
    \geq M(t_k - t + \frac{\Delta}{M}).
\]

Note that by virtue of our choice of \( t \), the right-hand side of the latter inequality is nonnegative. Therefore,

\[
    \int_{t_k}^{t_k+\frac{\Delta}{M}} |f(t)|^p dt \geq \int_{t_k}^{t_k+\frac{\Delta}{M}} M^p(t_k + \frac{\Delta}{M} - t)^p dt = M \int_0^{\frac{\Delta}{M}} s^p ds = \frac{M^p}{p+1} \left( \frac{\Delta}{M} \right)^{p+1}.
\]

Since the latter estimate holds uniformly for any \( k \), this implies \( \int_0^\infty |f|^{p+1} dt \) diverges, a contradiction. \( \square \)

Lemma 5. Let \( h \in L^q([0, \infty)) \), where \( q \geq 1 \), and let \( h \) have the bounded derivatives \( h', h'' \). Then,

\[
    \lim_{t \to \infty} h(t) = \lim_{t \to \infty} h'(t) = 0.
\]

Proof. Recall the standard notation: \( x^{[a]} = |x|^{a-1} x \), then \( x^{[a]}' = a|x|^{a-1} \). We have

\[
    \int_{t_0}^{t} |h'|^{2q} dt = \int_{t_0}^{t} \left( \frac{d}{dt} (h^{[2q-1]} h) - (2q-1) h'' h |h'|^{2q-2} \right) dt = h^{[2q-1]} h_{t_0}^{t} - (2q-1) \int_{t_0}^{t} h'' h |h'|^{2q-2} dt. \quad (A1)
\]

Using the boundedness of \( h, h' \) and subsequently Holder and Young’s inequalities gives

\[
    \int_0^{t} |h'|^{2q} dt \leq C_1 + C_2 \left( \int_0^{t} |h'|^{2q} dt \right)^{\frac{q-1}{q}} \left( \int_0^{t} |h|^q dt \right)^{\frac{1}{q}} \\
    \leq C_1 + \frac{C_2(q-1)}{q} e^{\frac{1}{q-1}} \int_0^{t} |h'|^{2q} dt + C_2 \frac{q}{q} \int_0^{t} |h|^q dt,
\]

implying for sufficiently small \( \epsilon \) that

\[
    \int_0^{t} |h'|^{2q} dt \leq C_3 + C_4 \int_0^{t} |h|^q dt.
\]

Since \( \| h \|_{L^q([0, \infty))} < \infty \), we obtain \( \| h' \|_{L^{2q}([0, \infty))} < \infty \); therefore, applying Lemma 4 to \( f = h' \) and \( p = 2q \), we deduce that \( \lim_{t \to \infty} h'(t) = 0 \). Furthermore, by the made assumptions, Lemma 4 is also applicable to \( f = h \) and \( p = q \geq 1 \); therefore, we have \( \lim_{t \to \infty} h(t) = 0 \), and the lemma follows. \( \square \)
Repeating the argument of the previous lemma one easily arrives to

**Corollary 3.** Let $h \in L^q([0, \infty))$, where $q \geq 1$, and let $h$ have the bounded derivatives $h^{(k)}$ of any order $k \geq 1$. Then,

$$h^{(k)} \in L^{2^{k q}}([0, \infty)) \quad \text{and} \quad \lim_{t \to \infty} h^{(k)}(t) = 0, \quad \forall k \geq 0.$$
