## Abstract

The goal of this thesis is to create an optimization model to optimize the routing of trains within railway stations. This problem is known as the train platforming problem, and the model we present is an integer programming model. By this model we aim to optimize factors such as walking distance, switch usage or platform usage.

We validate the model by implementing the model for Linköping station, which is a typical mid size station in the Swedish railway network. This implementation is done for different time horizons, ranging from 2 hours to one day, which corresponds to train sets ranging from 27 to 265 trains.

In the conclusion we see that the model is efficient for optimizing the train platforming problem for the implemented station and timetables, and that the model has a possibility to optimize the four objectives tested. Furthermore we see that optimizing certain objectives gives solutions that are also good with regards to other objective functions.

## Sammanfattning

Målet med den här uppsatsen är att skapa en optimeringsmodell för att optimera valet av vägar för tåg genom tågstationer. Modellen vi presenterar är en heltalsmodell, där syftet är att minimera bland annat gångavstånd, användningen av tågväxlar eller användningen av perronger.

För att testa modellen presenterar vi en implementation av modellen för stationen i Linköping, vilken är en typisk mellanstor station i det svenska tågnätet. Impplementeringen är gjord för olika tidslängder, från 2 timmar till ett dygn vilket motsvarar dataset från 27 till 265 tåg.

Vi drar slutsatsen att modellen på ett effektivt sätt kan lösa valet av tågvägar genom stationen, för de fyra tidtabeller och den station vi har implementerat. Vidare ser vi att modellen har potential att optimera de fyra målfunktioner vi testat och att optimering av några av målfunktionerna ger lösningar som är bra även med hänsyn till de andra målfunktionerna.

## Acknowledgements

I would like to thank my supervisors Anders Peterson and Fredrik Johansson for introducing me to the subject of train scheduling and suggesting the problem. I would also like to thank Kaj Holmberg for taking his time to be the examiner of this thesis. Last but not least i would like to thank family and friends for their support.

## Nomenclature

## Notation

$\mathcal{T}$ The set of all trains
$\mathcal{P}$ The set of all platforms
$\mathcal{R}$ The set of all routes
$\tau_{t}^{a} \quad$ Arrival time of train $t$
$\tau_{t}^{d} \quad$ Departure time of train $t$
$d_{t}^{a} \quad$ Arrival direction of train $t$
$d_{t}^{d} \quad$ Departure direction of train $t$

## Chapter 1

## Introduction

There are multiple different reasons for improving the railway. Travel by railway needs to become more attractive to meet the future's demands for more energy efficient transport. This motivates both the development of new and more efficient technologies and infrastructure, but also optimizing the current railway to make it more attractive to customers. There are also economic motivations. According to the Swedish transport administration the maintenance of the Swedish railway costs 6 billion Swedish crowns annually [21]. Also the production of new railway is much more expensive compared to the costs to produce new roads. It is therefore of interest to make optimal use of the infrastructure that is already in use.

One way to improve the railway is the way track owners work with train scheduling. Scheduling of trains primarily consists of setting time tables, choosing which routes the train takes and which platforms it will stop at, and finally the scheduling of stock and personnel. These phases can be seen as independent from one another, or be treated simultaneously. Traditionally train scheduling has been performed manually by train planners based on some simple rules and experience, which made it a time consuming and difficult task.

In train scheduling, the stations play a critical role. According to calculations made by the Swedish transport administration, passengers value time in transit between two methods of transportation 2.5 times as much as time spent in vehicle [20]. Due to the layout of most train stations, changing from one train to another can be difficult for those who are movement impaired. Hence we can optimize train routing for minimal walking distance between train changes to improve the passenger experience.

The routing of trains, especially inside stations, is a very complex problem. This is since the routing of one train highly affects the options for how we can route other trains. This is due to that each train needs a section of track ahead reserved, and during this reservation no other trains can occupy this section of track. Because of this, the delay of one train will affect the routing of other trains and create delay propagation.

The problem of assigning trains to routes and platforms inside a train station is known as the train platforming problem. Usually this is done in two phases. Firstly when the time table is set to assure that there is a fesable assignment of trains to routes. Secondarily the train platforming problem arises when one or more trains is delayed which creates a need to redo some or all platforming until all trains are running on time again.

There are many ways to model and optimize the train platforming problem (for more on the previous research see Chapter 3), in this thesis i will primarily use Integer Linear Programming.

### 1.1 Problem description

The primary objective of this thesis is to develop a mathematical model that can create practically possible assignments of trains to routes, and that can optimize the assignments for several different objectives. Such objectives include to minimize the number of platforms used, minimizing walking distance or assigning trains to platforms as close to the station entrance as possible.

Secondarily we want to compare the results when optimizing for the different objectives, and investigate how the different objectives are affected when optimizing for other objectives. The purpose of this is to see what properties can be optimized and to see at what expense.

For the sake of validation we present the results from an implementation of four different timetables for Linköping station, which is a quite typical mid-size railway station.

### 1.2 Approach and Method

To solve the train platforming problem we will use mathematical optimization, which is motivated by the large amount of previous research on similar problems that use optimization.

It turns out that the problem can be conveniently formulated as an integer linear program. The model will be implemented in AMPL and solved using the CPLEX solver

### 1.3 Delimitations

To restrict the problem to a feasible scope for the project a certain number of delimitations are needed. We will assume that we only control the train traffic inside the station, that is that we have a given direction of arrival and departure for each train that can not be changed. We will furthermore assume that the timetable is fixed and can't be changed, and that each train arrives and departs on time.

The goal is to develop a model that can work for any train station. To prove that the model works we will provide an implementation of the model at Linköping Central station. Furthermore, we will not consider shunting decisions in the model, or in which order the trains are stored on the storage tracks.

### 1.4 Structure of the thesis

Chapter 2 contains a few preliminaries that are needed to understand the rest of the thesis. In chapter 3 we present a survey of some previous research on train platforming and other similar problems. The main contribution on the report is presented in Chapter 4, where the optimization model is presented, and an implementation for Linköping is presented in chapter 5. Chapter 6 contains the results of the implementation and finally the Conclusion and discussion is in chapter 7, along with suggestions for further research.

[^0]
## Chapter 2

## Preliminaries

The purpose of this chapter is to give the necessary prerequisites to understand the results and to introduce the notations and conventions used in the rest of this thesis.

### 2.1 Optimization

The results of this thesis relies on the subject of mathematical optimization. For a more complete introduction to the subject, see the books Holmberg (2018) [11] or Lundgren et al. (2010) [16]. The following sections aims to introduce the notation that will be used in the rest of this thesis, and some results that are of special interest for the result.

Definition (Integer Linear Programming problem)

$$
\begin{gather*}
\min z=c^{T} x  \tag{2.1}\\
\mathbf{A} x \leq b \\
x_{i} \in \mathbb{N}
\end{gather*}
$$

The optimal value for the ILP is denoted as $z_{I P}^{*}$. If we replace the variables with $x_{i} \in\{0,1\}$ we call the problem a binary integer problem.

Definition (LP Relaxation)
The LP relaxation of the integer problem in equation 2.1 is the problem

$$
\begin{equation*}
\min z=c^{T} x \tag{2.2}
\end{equation*}
$$

Calderon, 2022.

$$
\begin{gathered}
\mathbf{A} x \leq b \\
x_{i} \geq 0
\end{gathered}
$$

The optimal value for the LP-relaxation is denoted as $z_{L P}^{*}$.
Definition (Totally unimodular matrix) A matrix is said to be totally unimodular if and only if all the determinants of all its square submatrices are $\pm 1$ or 0 .

Definition (The integrality property) An IP-problem is said to have the integrality property if the optimal solution to the LP-relaxation is also a valid in the original IP-problem. In other words that is if $z_{I P}^{*}=z_{L P}^{*}$. A IP-problem has the integrality property if the matrix $\mathbf{A}$ is totally unimodular.

Defnition (Canonical linearisation). Given two binary variables $x_{1}$ and $x_{2}$, then we can transform the term $x_{1} x_{2}$ to a linear term by introducing a new variable $w=x_{1} x_{2}$. To make sure that $w$ takes the right value based on $x_{1}$ and $x_{2}$ we introduce the constraints $x_{1} \geq w, x_{2} \geq w$, and $x_{1}+x_{2}-1 \leq w$.

## Chapter 3

## Literature review

Multiple different research teams have worked on some version of the train platforming problem. However, each team have worked on quite different variants of the problem and have used different methods. The literature will be presented in three sections. The main focus is the first section which presents previous research on ILP and MILP models. Section 2 contains examples of other approaches for the TPP, and the third section is about research on similar problems to the TPP.

### 3.1 ILP and MILP methods

In three papers by Zwaneveld et al. from 1996, 1997 and 2001 ([24], [13] and [25]) the authors present a model to maximize the number of trains from a given timetable that can be assigned to a route through the station. Each platform and train combination is given a weight $\rho_{t, p}$ to model certain preferences for trains to stop at particular platforms.

The authors assume that each arrival and departure time, and the directions of arrival and departure are known a priori. The model used in the papers assume a cyclic timetable with length 60 minutes.

In the paper [24] the authors examine the computational complexity of the model, and conclude that if each train has more than three routes to choose from then the TPP is NP-complete. Furthermore Zwaneveld et. al. concluded that if each train has at most two routes to choose from, then the problem can be solved in $\mathcal{O}\left(|\mathcal{T}|^{2}\right)$, where $\mathcal{T}$ is the set of trains.

Finally in the paper [25] the authors show that their version of the TPP can be viewed as a weighted node packing problem. Each route and train combination is given a vertex and each vertex pair that correspond to the same train is an edge in the graph. Also each pair of incompatible assignments of trains to routes corresponds to an edge.

The authors introduce some preprocessing procedures and an algorithm for solving the weighted node packing problem, based on a branch and cut approach.

The model treated by Carprara et al. in [4] is a very general model with many things taken into consideration. Each train is only given an ideal arrival and departure time, and is allowed to shift from the ideal times by some set limit.

Furthermore a set of dummy platforms are introduced to handle potential trains over the capacity of the station. Each platform is associated with a cost, where the cost of the dummy platforms are significantly bigger than the costs of the ordinary platforms.

Each train is given a priority and a cost based on the priority of the train and how much the time is shifted from the ideal time given an assignment to a particular route. The model contains two types of incompatibilities between routes. There are those who are considered hard incompatibilities which are handled in the constrains of the model. There are also soft incompatibilities between routes, that can be violated at a certain cost.

To handle the costs of the soft incompatibilities Carprara et. al. get a square term in the objective function. In contrast to some other papers, the authors of [4] refrain from using the canonical linearisation, claiming that the resulting LP-relaxation would be too weak. Instead they make use of a set of clique inequalities from the graph of incompatible routes. This yields more constraints, but a tighter bound for the LP-relaxation.

The objective function used is a weighted sum of the costs of platforms, the costs associated with the used routes and the soft incompatibilities. The resulting model is too complex to solve explicitly, so the authors solve by branch and cut. The authors conclude that their model is able to improve the capacity of the three stations considered.

Petering et al [18 studied a combined timetabling and platforming problem. The objective was to create an cyclic timetable with as minimal cycle time, and
to minimize journey times for each train. After implementing various preprocessing steps to reduce constraints and to make the model as efficient as possible, the authors present the results for several data sets with between 3 and 6 train lines.

Yet another approach is taken by Chakroborty and Vikram in [7. They base their model around the assumption that arrival times of trains is only known one hour in advance. Furthermore the model takes into account that trains may need to be halted outside the station if all tracks happen to be occupied at the same time.

The authors formulate their model as a MILP-model with the objective to minimize trains that need to wait outside the station and maximizing assignments to preferred platforms. The authors conclude that for data sets up to 110 trains that the model has a short solve time.

In the paper by Akyol et. al. [1] the authors show that the TPP can be viewed as a parallel machine scheduling problem, and can be model using binary integer models used for the machine scheduling problem. Doing this lets the trains deviate from the original timetable, and the objective becomes to minimize this deviation. In a similar manner Zeng et. al [23] formulated the problem as a Job shop scheduling problem.

### 3.2 Other approaches

### 3.2.1 Graph theoretical approaches

One of the earliest studies of the train platforming problem was in a paper from 1998 by De Luca Cardillo and Mione [8] where they study the k L-list $\tau$ colourings of graphs. The main objective of the paper was to present an effective heuristic for finding a L-List $\tau$ colouring for a given $k$.

They do however present a representation of the train platforming problem that can be viewed as k L-list $\tau$ colouring of a graph. If we let the vertex set be the set of trains, and introduce some parameter $I_{\text {min }}$, corresponding to the minimum time between trains at a platform, then we can define the edges such that $\left(t_{1}, t_{2}\right) \in E$ if the arrival times differ by less than $I_{\text {min }}$.

By letting the set of colours equal the set of platforms and $\tau$ the set of incompatible assignments the problem can be viewed as a $k$ L-list $\tau$ colouring.

Note that in this instance of the problem choosing a platform is the same as choosing a route. In other words, if we know where the train enters the station, where it exits the station, and which platform it stops at, then we also know the route of the train through the station. Furthermore the authors test the implementation of the heuristic for six scenarios, ranging from 41 to 242 trains, and from 5 to 21 tracks.

### 3.2.2 Heuristic approaches

Another variant of the problem was treated in a paper from 2003 by Carey and Carville [5].

One property that is unique for this model is that some platforms can be split into subplatforms where multiple trains can stop, one at each subplatform. This adds a lot of complexity in how assignment of a train to a given platform affects what other assignments are valid.

In contrast to most other papers, the goal of the authors in [5] is not to solve the train platforming problem using an optimization model, but instead to present an heuristic algorithm to solve the problem. The goal for the algorithm was not in the first place to solve the problem optimally, but instead to create a feasible solution, similar to those assignment created by train planners.

### 3.2.3 Real Time Dispatching

Most other papers considers solving the TPP in a planning context, long before the trains are supposed to run. Another situation where there is a need to route trains through stations is the real time situation. Since one delayed train affect the possible routings of other trains and might create further delays, dispatchers need to assign new departure times and routes in real time. This is known as the real time dispatching problem.

Such a situation is treated by Lamorgese and Mannino in [14. The authors does not restrict the model to one line or one station, but instead formulate a model for the whole network. They proceed to present a model where the problem for the whole network can be decomposed into a problem for each station and one for each line. This model is solved similarly to how a Benders decomposition works, where the line problem acts as the master problem and the station acts as the slave problem.

### 3.2.4 Non-linear models and Max-plus automatas

In the paper [22] by Wang and Yue, the authors treat the platforming problem as a multi objective mixed integer non-linear problem, where the constraints are linear but one of the objective functions are not linear. Each train is given a preferred platform and the first objective is to maximmize the number of trains assigned to preferred platforms. The second objective function is to have a balanced use of the tracks. These objective functions are then weighted together. The authors found that for a timespan of three hours for a busy station the model was efficient at creating optimal assignments.

One of the later contributions on the topic of train platforming is the research presented by Besinovic and Goverde in [2]. In this paper the authors goal is to optimize for stability and minimize delay propagation. In contrast to many other recent papers the authors does not solve the optimization problem using integer problem programming, but instead uses a Max-plus automata.

### 3.3 Related research

### 3.3.1 Gate assignment at airports

A similar problem to the train platforming problem is the assignment of airplane to gates at an airport. One difference is that if need be not every plane needs to be assigned to a gate, instead planes can be assigned to load and unload passengers outside at the tarmac. Another difference to the TPP is that assignment of a plane to a given gate does not affect the possibility to assign other planes to other gates.

One of many examples where this problem has been studied is in the paper [10] by Ding et al, where the authors model the problem as a quadratic integer problem. In this model the authors use a multi objective optimization approach with two objective functions. The primary goal is to maximize the number of planes that are assigned to gates, and the secondary objective is to minimize the walking distance within the gates.

### 3.3.2 Allocation at bus stops

Another problem that is the somewhat similar is the allocation of bus lines at transit terminals. In contrast to the train platforming problem, the problem is to allocate whole lines (i.e. "all buses from Norrköping to Finspång arrive and depart from stop B2"). The constraints for the problem is very similar to the

TPP, with each line has to be assigned to one stop, we can't have two or more buses at the same stop at the same time.

One example of a paper that studies this type of problem is Lindberg et. al. in [15]. The authors present an integer linear optimization model to minimize the walking distance. To handle simultaneous assignments the authors use the canonical linearisation. Furthermore the authors compare their optimization model with random assignments and with assignment based on non transferring passengers. The conclusion presented in [15] is that the optimization model presented can on average improve the walking distances by $13 \%$, compared to random assignments.

### 3.4 Summary and conclusion of literature review

In conclusion there have been many variants of the platforming problem studied, many more than the sample above. There are multiple different approaches to create valid assignments such as integer programming, graph colourings, automatas or certain algorithms.

Furthermore, most of the papers considered puts the objective as improving capacity of stations, or minimizing error propagation. The passenger perspective such as walking distance or optimizing for cross platform transits is rarely considered. We also see that the train platforming problems is very complex and gets difficult to solve quickly if the numbers of possible routes gets large. Most papers resort to heuristical approaches.

## Chapter 4

## Optimization model

In this chapter we propose an optimization model for the train platforming problem.

### 4.1 Properties of the station and parameters

For a given railway station we have some set of platforms $\mathcal{P}$, which are sections of track where trains can stop and passengers can board and alight the train. We also have a set $\mathcal{D}$ of directions, which can be tracks in and out from the station, or storage tracks where trains not in use are stored. The directions can also be tracks towards a shunting area of the station.

For example, see the fictitious train station in figure 4.1. We have that $\mathcal{P}=$ $\{P 1, P 2, P 3, P 4\}$, and set of directions are $\mathcal{D}=\{D 1, D 2, D 3, D 4, D 5, U 1, U 2\}$.

Due to some platforms being shorter than some of the longer trains there are restrictions on which train can stop at which platform. To model this compatibility we create the parameter $c_{p, t}$, where $c_{p, t}=1$ if train $t$ can stop at platform $p$, and $c_{p, t}=0$ otherwise.

For each pair of a platform $p \in \mathcal{P}$ and a direction $d \in \mathcal{D}$ there is a set of possible routes $\mathcal{R}_{p, d}$ linking the two. We denote the set of all routes at the station as $\mathcal{R}$. We will assume that all routes are known in advance, either by generated by manual calculation or by implementation of some route generating algorithm. An example of such an algorithm can be found in [17].

Figure 4.1: The layout of the tracks at a fictitious train station.

When a train arrives at the station a route is reserved from from the arrival point to the platform. During this time no other trains can use any section of track in this route. When the train has passed a section of track the section becomes no longer reserved. Similarly when a train leaves the platform a route is reserved from the platform to the point where the train exits the station.

In the model however the whole route is reserved for the train from the point it enters the station, until it stops at the platform, and then the whole outward route is reserved from when the train leaves the platform until the train has left the station.

Two routes is said to overlap if there is some section of tracks used by both routes. During the time that a route is reserved no other routes which overlap with the route can be used. To keep track of which routes overlap we let $a_{r, r^{\prime}}=1$ if the routes $r$ and $r^{\prime}$ overlap, otherwise $a_{r, r^{\prime}}=0$. Take for example the routes $r_{1}$ from $D 5$ to $P 1$ and $r_{2}$ from $U 1$ to $P 2$. Since these two routes share a section of track we have $a_{r_{1}, r_{2}}=1$

During the allotted time window we are to assign a set of trains $\mathcal{T}$ to platforms and routes. Each train $t \in \mathcal{T}$ has a given arrival time $\tau_{t}^{a}$ and a given departure time $\tau_{t}^{d}$, which are the times that the train arrives to or departs from the platform. Furthermore we have an arrival direction $d_{t}^{a} \in \mathcal{D}$ and a departure
direction $d_{t}^{d} \in \mathcal{D}$ for each train. The trains also has a number of passengers $n_{t}$ that are to board or alight the train.
$\Pi$ is the headway between trains at a given platforms, i.e. the time window required between two trains at the same platform for safety reasons. $\Xi$ is the time it takes for the train to leave the station after leaving the platform, or the time it takes for the train from entering the station until it stops at the platform. In reality this depends on the route, the type of trains etc, but in the model we will assume the same headway for all train and route combinations.

We need to keep track of which trains are at the platforms simultaneously, to model the fact that each platform only can accommodate for one train at the time. To do this we introduce the set $\mathcal{E}_{x} \subseteq \mathcal{T} \times \mathcal{T}$, which consists of all pairs of trains that are at a platform during the same time.

In more detail we say that $\left(t_{1}, t_{2}\right) \in \mathcal{E}_{x}$ if $\left(\tau_{t_{1}}^{a}-\Pi / 2, \tau_{t_{1}}^{d}+\Pi / 2\right) \cap\left(\tau_{t_{2}}^{a}-\Pi / 2, \tau_{t_{2}}^{d}+\right.$ $\Pi / 2) \neq \emptyset$. This is equivalent to the arrival and departure times satisfying the inequality $\left(\tau_{t_{1}}^{d}-\tau_{t_{2}}^{a}+\Pi\right)\left(\tau_{t_{2}}^{d}-\tau_{t_{1}}^{a}+\Pi\right)<0$. An example can be seen in figure 4.2 .

Figure 4.2: Three examples of how two time windows can relate to each other. In A the time windows does not overlap and hence $\left(\tau_{t_{2}}^{d}-\tau_{t_{1}}^{a}+\Pi\right)\left(\tau_{t_{2}}^{d}-\tau_{t_{1}}^{a}+\Pi\right)<0$. In B we have a partial overlap and in C a total overlap. In both B and C we have that $\left(\tau_{t_{2}}^{d}-\tau_{t_{1}}^{a}+\Pi\right)\left(\tau_{t_{2}}^{d}-\tau_{t_{1}}^{a}+\Pi\right) \geq 0$. In B and C we have that the pair $\left(t_{1}, t_{2}\right)$ belongs to $\mathcal{E}_{x}$, but this is not the case in A .

In a similar way we need to model incompatible assignments of routes for departure and arrival. This yields three cases, two arriving trains, two departing trains, and an arriving and a departing train.

The first two cases can be modelled in the same manner as the platform assignments. We create the sets $\mathcal{E}_{y} \subseteq \mathcal{T} \times \mathcal{T}$ and $\mathcal{E}_{z} \subseteq \mathcal{T} \times \mathcal{T}$, where $\left(t_{1}, t_{2}\right) \in \mathcal{E}_{y}$ or $\left(t_{1}, t_{2}\right) \in \mathcal{E}_{z}$ if $\left(t_{1}, t_{2}\right)$ satisfy 4.1 respectively 4.2

$$
\begin{align*}
& \left(\tau_{t_{1}}^{a}-\Xi, \tau_{t_{1}}^{a}\right) \cap\left(\tau_{t_{2}}^{a}-\Xi, \tau_{t_{2}}^{a}\right) \neq \emptyset  \tag{4.1}\\
& \left(\tau_{t_{1}}^{d}, \tau_{t_{1}}^{d}+\Xi\right) \cap\left(\tau_{t_{2}}^{d}, \tau_{t_{2}}^{d}+\Xi\right) \neq \emptyset \tag{4.2}
\end{align*}
$$

The conditions 4.1 and 4.2 are equivalent to $\left(t_{1}, t_{2}\right)$ satisfying the inequalities 4.3 respectively 4.4 .

$$
\begin{align*}
& \left(\tau_{t_{2}}^{a}-\tau_{t_{1}}^{a}+\Xi\right)\left(\tau_{t_{1}}^{a}-\tau_{t_{2}}^{a}+\Xi\right)<0  \tag{4.3}\\
& \left(\tau_{t_{2}}^{d}-\tau_{t_{1}}^{d}+\Xi\right)\left(\tau_{t_{1}}^{d}-\tau_{t_{2}}^{d}+\Xi\right)<0 \tag{4.4}
\end{align*}
$$

To model the third case we need the set $\mathcal{E}_{y z} \subseteq \mathcal{T} \times \mathcal{T}$. In the contrast to the other cases the order of the pair is important, that is that $\left(t_{1}, t_{2}\right) \in \mathcal{E}_{y z}$ equivalent to $\left(t_{2}, t_{1}\right) \in \mathcal{E}_{y z}$. A pair of trains $\left(t_{1}, t_{2}\right)$ is in $\mathcal{E}_{y z}$ if $\left(\tau_{t_{1}}^{a}-\Xi, \tau_{t_{1}}^{a}\right) \cap\left(\tau_{t_{2}}^{d}, \tau_{t_{2}}^{d}+\Xi\right) \neq \emptyset$. In other words $t_{1}$ is the arriving train and $t_{2}$ is the departing train. This condition is equivalent to the times satisfying the inequality $\left(\tau_{t_{1}}^{a}-\tau_{t_{2}}^{d}\right)\left(\tau_{t 2}^{d}-\tau_{t_{1}}^{a}+2 \Xi\right)<0$.

### 4.2 Model

Based on the data given above we formulate the following model

$$
\begin{gather*}
\min f(x, y, z, w)  \tag{4.5}\\
\sum_{p \in \mathcal{P}} c_{t, p} x_{t, p}=1 \quad t \in \mathcal{T}  \tag{4.6}\\
\sum_{r \in \mathcal{R}_{p, d_{t}^{a}}^{a}} y_{t, r}=x_{t, p} \quad p \in \mathcal{P}, t \in \mathcal{T}  \tag{4.7}\\
\sum_{r \in \mathcal{R}_{p, d_{t}^{d}}} z_{t, r}=x_{t, p} \quad p \in \mathcal{P}, t \in \mathcal{T}  \tag{4.8}\\
x_{t_{1}, p}+x_{t_{2}, p} \leq 1 \quad p \in \mathcal{P} \quad\left(t_{1}, t_{2}\right) \in \mathcal{E}_{x}  \tag{4.9}\\
a_{r_{1}, r_{2}} y_{t_{1}, r_{1}}+a_{r_{1}, r_{2}} y_{t_{2}, r_{2}} \leq 1 \quad r_{1}, r_{2} \in \mathcal{R} \quad\left(t_{1}, t_{2}\right) \in \mathcal{E}_{y} \tag{4.10}
\end{gather*}
$$

$$
\begin{gather*}
a_{r_{1}, r_{2}} z_{t_{1}, r_{1}}+a_{r_{1}, r_{2}} z_{t_{2}, r_{2}} \leq 1 \quad r_{1}, r_{2} \in \mathcal{R} \quad\left(t_{1}, t_{2}\right) \in \mathcal{E}_{z}  \tag{4.11}\\
a_{r_{1}, r_{2}} y_{t_{1}, r_{1}}+a_{r_{1}, r_{2}} z_{t_{2}, r_{2}} \leq 1 \quad r_{1}, r_{2} \in \mathcal{R} \quad\left(t_{1}, t_{2}\right) \in \mathcal{E}_{y z}  \tag{4.12}\\
x_{t, p} \in\{0,1\} \quad y_{t, r} \in\{0,1\}, \quad z_{t, r} \in\{0,1\} \tag{4.13}
\end{gather*}
$$

The model contains three sets of variables: $x_{t, p}$ which indicates if train $t$ is assigned to platform $p, y_{t, r}$ indicating if train $t$ is assigned to route $r$ as an arrival route, and $z_{t, r}$ indicating if train $t$ is assigned to route $r$ as a departure route.

No particular objective function is specified here since the model is compatible with many different objective functions, more on that in the next section.

Constraint 4.6 assures that each train is assigned to one and only one compatible platform, while constraints 4.7 and 4.8 makes sure that if a train is assigned to a platform it is also assigned to a route to that platform.

Constraint 4.9 assures that if two trains can not be assigned to the same platform if their time windows overlap. Similarly the constraints 4.10 4.11, and 4.12 ensures that if two overlapping routes are used, then the time windows for when the routes are used does not overlap.

### 4.3 Objective functions

The model described above can be combined with numerous different objective functions. For the purpose of this thesis we want to compare objective functions that somehow relate to the passenger experience with objectives that improve different aspects of the railway operation. We have chosen four different objective functions that seek to minimize walking distance to station, total walking distance, switch usage and numbers of platforms in use.

Denoting $\delta_{p}$ as the walking distance from the platform $p$ to the station entrance and exit, and $n_{t}$ the number of passengers that are to board or alight on the train $t$, then we can minimize the total walking distance for passengers that are leaving or entering the station. This gives the objective function $f_{1}$ seen in equation 4.14

$$
\begin{equation*}
f_{1}(x)=\sum_{p \in \mathcal{P}} \sum_{t \in \mathcal{T}} n_{t} \delta_{p} x_{t, p} \tag{4.14}
\end{equation*}
$$

We can also take into account the number of passengers that are changing from one train to another. If we know the walking distances between platforms $\delta_{p, p^{\prime}}$, and the number of passengers $n_{t, t^{\prime}}$ switching from train $t$ to $t^{\prime}$, then we can
minimize the total walking distance as the objective function
However to do this we need the capacity to model the simultaneous assignment of trains $x_{t, p} x_{t^{\prime}, p^{\prime}}$. To preserve the linearity of the problem we make use of the cannonical linearization and introduce the variable $w_{t, t^{\prime}, p, p^{\prime}}=x_{t, p} x_{t^{\prime}, p^{\prime}}$ and constraints 4.15, 4.16 and 4.17. This lets us model the total walking distance with the function 4.18, which is the same objective function as in [15.

$$
\begin{gather*}
w_{t, t^{\prime}, p, p^{\prime}} \leq x_{t, p} \quad p, p^{\prime} \in \mathcal{P}, t, t^{\prime} \in \mathcal{T}  \tag{4.15}\\
w_{t, t^{\prime}, p, p^{\prime}} \leq x_{t^{\prime}, p^{\prime}} \quad p, p^{\prime} \in \mathcal{P}, t, t^{\prime} \in \mathcal{T}  \tag{4.16}\\
w_{t, t^{\prime}, p, p^{\prime}} \geq x_{t, p}+x_{t^{\prime}, p^{\prime}}-1 \quad p, p^{\prime} \in \mathcal{P}, t, t^{\prime} \in \mathcal{T}  \tag{4.17}\\
f_{2}(x, w)=\sum_{t \in \mathcal{T}} \sum_{t^{\prime} \in \mathcal{T}} \sum_{p \in \mathcal{P}} \sum_{p^{\prime} \in \mathcal{P}} \delta_{p, p^{\prime}} n_{t, t^{\prime}} w_{t, t^{\prime}, p, p^{\prime}}+\sum_{p \in \mathcal{P}} \sum_{t \in \mathcal{T}} n_{t} \delta_{p} x_{t, p} \tag{4.18}
\end{gather*}
$$

One of the more sensitive elements of the railway are the switches where different tracks meet. Switches sometimes break and require money and time for upkeep. It would therefore be of interest to minimize switch usage.

If we denote the number of switches in a given route as $s_{r}$, then we can formulate the objective function to be the number of switches passed in total, which give the objective function

$$
\begin{equation*}
f_{3}(y, z)=\sum_{t \in \mathcal{T}} \sum_{r \in \mathcal{R}} s_{r}\left(y_{t, r}+z_{t, r}\right) . \tag{4.19}
\end{equation*}
$$

There might also be interest to minimize the numbers of platforms that are in use. If a platform could be removed, we could also remove several switches and sections of track, which would in turn mean less money spent on upkeep. A station with fewer platforms might also be less confusing from a passenger perspective.

To implement such an objective function we need a few additional variables and constraints. If we define a binary variable $h_{p}$ to indicate if platform $p$ is used or not, and add the constraint $x_{t, p} \leq h_{p}$, then we can formulate the objective function as

$$
\begin{equation*}
f_{4}(h)=\sum_{p \in \mathcal{P}} h_{p} . \tag{4.20}
\end{equation*}
$$

## Chapter 5

## Implementation

### 5.1 Implementation at Linköping Station

To test our model we have implemented the model for Linköping central station. This is a mid-size station, typical for the Swedish railway network. Various types of traffic pass through the station, including commuter trains, cargo trains and long distance trains. Adjacent to the railway station there is a bus station for both local and regional bus traffic. Note that no cargo trains stop at the station, but there are several that pass through the station, and that this is modelled as the cargo trains having the same arrival- and departure time.

The layout for the station can be seen in figure 5.1. This is only an approximation, but it is this layout that will be used for the implementation. In reality passengers can exit the station at both sides, but in the model we will assume that the passengers exit and enter at the side which is closest to $P 1$.

Figure 5.1: The layout of the tracks at Linköping central station

The station has three physical platforms, between $P 5$ and $P 4$, between $P 3$ and $P 2$, and adjacent to $P 1$. Platforms $1-3$ is long enough to accommodate all trains, where platforms 4 and 5 only are compatible with the shorter commuter trains. For detailed information regarding the platform compatibility in the implementation see appendix B.

The directions $D 1, D 2, D 3, D 4$ are the southern main line (Södra stambanan) and the direction $D 5$ is the line towards Kalmar and Västervik (Stångådalsbanan/ Tjustbanan). Besides the main directions we have four storage tracks for trains $U 1, U 2, U 3$, and $U 4$.

The possible routes for the station $\mathcal{R}$ were calculated by hand. This yielded 43 routes in total. On average each possible platform and direction combination has one possible route, with some combinations having more than one route. On the other hand, for example the combination $D 2$ and $P 1$ had no possible routes, since trains are not allowed to go backwards. The complete list of routes can be found in linköping.dat in appendix A.

### 5.2 Data

### 5.2.1 Timetables

The model is implemented for four different timetables denoted as by A-D. The timetables were based on the real timetable from April 1st 2021, which is a day with quite typical traffic. The real timetables can be found at [12] for the passenger trains and at 19 for the cargo trains.

A summary of the timetables can be found in table 5.1, and the full timetables can be found in Appendix B. The timetable D consists of all trains in a day, which is the longest time horizon that is interesting to optimize. This is due to that are very few or no trains that pass through the station during the night, which in turn leads to that platforming for one day have little to no impact on the platforming the next day.

| Timetable | Start | Stop | $\|\mathcal{T}\|$ |
| :--- | :--- | :--- | :--- |
| A | $11: 00$ | $13: 00$ | 27 |
| B | $07: 00$ | $09: 00$ | 32 |
| C | $07: 00$ | $13: 00$ | 83 |
| D | $00: 00$ | $23: 59$ | 265 |

Table 5.1: A summary of the timetables used in the implementation.

For trains that arrive and depart the station we assume the convention of left hand traffic, and therefore trains arrive at $D 2$ and $D 4$, and depart at $D 1$ and D3. Since Stångådalsbanan and Tjustbanan share a single track for the first part from Linköping trains both depart towards and arrive from $D 5$.

No data was given about the departure direction and times of the trains that terminate at Linköping. Similarly no data of arrival time and directions was available for the trains that start at Linköping station. For those trains data was generated in the following manner.

- If a train terminates at Linköping and within 15 minutes a new train of the same type starts from Linköping then these two trains are assumed to be the same train.
- Otherwise we assume that the train stays five minutes at the station and departs to/arrives from some storage track. This storage track was arbitrarily chosen, with the same storage track for each train on the same line.

The arrival and departure directions of each train is included in appendix B. The capacity for each storage track is not considered, it is only assumed to be sufficient.

### 5.2.2 Passengers

The number of passengers where estimated in proportion to be half of the maximum number of passengers on each train type. Maximum number of passengers for each train can be found along with the timetables in Appendix $B$.

When optimizing for the objective function $f_{2}$ in equation 4.18, we need to know how many passengers will change from one train to another. This data was estimated as follows: if two trains depart more than one hour apart we assume that no passengers changes between these two trains.

Furthermore we assume that passengers are unlikely to change from one train to another of a similar type, that is for example changing from one commuter train on the line Linköping to Motala to another train on the same line. Besides these two restrictions we assume that passengers changes between all possible trains.

In the case for $f_{2}$ we assume that $40 \%$ of the maximum of passengers does not change trains, but instead arrive or depart from the station entrance. Furthermore we assume that $10 \%$ of max passengers changes to another train, equally distributed to all the available trains to change to.

The ratio between switching and non switching passengers were difficult to measure due to the ongoing coronavirus pandemic, and no data about travel before the pandemic was available to us. The ratio suggested above is a very rough estimate and we will compare different values later in a sensitivity analysis in section 6.5.

### 5.2.3 Linköping station

The walking distance between platforms are measured in a number of tracks needed to cross to get from the station entrance to the platform. Hence $\delta_{1}=0$, $\delta_{2}=\delta_{3}=1$ and $\delta_{4}=\delta_{5}=2$. By similar reasoning the values for $\delta_{p, p^{\prime}}$ was approximated, the values can be found in Table 4.2.

| $\delta_{p, p^{\prime}}$ | P 1 | P 2 | P 3 | P 4 | P 5 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| P1 | 0 | 1 | 1 | 1 | 1 |
| P2 |  | 0 | 0 | 1 | 1 |
| P3 |  |  | 0 | 1 | 1 |
| P4 |  |  |  | 0 | 0 |
| P5 |  |  |  |  | 0 |

Table 5.2: The distances between platforms at Linköping station
In the implementation we assume that $\Pi=1 \mathrm{~min}$ and $\Xi=1 \mathrm{~min}$.

## Chapter 6

## Results

The purpose of this chapter is to present the results of the implementation at Linköping which was presented in chapter 4 . We will also investigate which is the maximal headway for which a valid solution exists.

The implementation was done in AMPL using the CPLEX solver, the code for which can be found in Appendix A. The code was run on a laptop with an 1.8 Ghz processor and 8 GB of internal memory. The AMPL presolve setting was enabled, which eliminated some variables and constraints for the purpose of reducing solve time.

### 6.1 Timetable A

The timetable A is based on a time window from 11:00 to $13: 00$, which is a period with relatively low traffic. The running times for optimizing for the four different objective functions, can be found in table 6.1. In this table Variables and Constraints denote the numbers before the presolve, while Variables* and Constraints* are after the presolve. All data in table 6.1 refer to the IP problem.

|  | Time | Variables | Constraints | Variables* | Constraints* |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $f_{1}^{*}$ | 0.343 s | 2187 | 2815 | 553 | 2760 |
| $f_{2}^{*}$ | 5.812 s | 20412 | 57490 | 14710 | 44763 |
| $f_{3}^{*}$ | 0.047 s | 2187 | 2815 | 2148 | 2760 |
| $f_{4}^{*}$ | 0.031 s | 2192 | 2950 | 557 | 2852 |

Table 6.1: Running times, variables and constraints.

Most notably is how $f_{2}$ is much more complex due to the added canonical linearisation. We are interested in how optimizing for one objective function affects the value of the other objective functions. A comparison of the values can be found in table 6.2. Comparisons between the LP and IP optimum can be found in table 6.3

|  | $f_{1}^{*}$ | $f_{2}^{*}$ | $f_{3}^{*}$ | $f_{4}^{*}$ |
| :--- | :--- | :--- | :--- | :--- |
| $f_{1}$ | 969.589 | 1050.6 | 1169.91 | 3148.05 |
| $f_{2}$ | 1468.96 | 1404.62 | 1516.87 | 3490.22 |
| $f_{3}$ | 212 | 193 | 152 | 324 |
| $f_{4}$ | 5 | 4 | 4 | 3 |

Table 6.2: Comparison of values for the objective functions.

|  | $f_{1}^{*}$ | $f_{2}^{*}$ | $f_{3}^{*}$ | $f_{4}^{*}$ |
| :--- | :--- | :--- | :--- | :--- |
| LP optimum | 969.589 | 1371.69 | 152 | 1.5 |
| IP optimum | 969.589 | 1404.62 | 152 | 3 |

Table 6.3: Comparison of values between the original problem and its LP relaxation.

Notably we see that LP optimum and IP optimum is the same for $f_{1}$ and $f_{3}$.

### 6.2 Timetable B

Timetable B is the trains between 07:00 and 09:00, which is a more traffic intense period than the one of timetable $A$.

|  | Time | Variables | Constraints | Variables* | Constraints* |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $f_{1}^{*}$ | 0.125 s | 2592 | 7786 | 684 | 6995 |
| $f_{2}^{*}$ | 13.376 s | 28192 | 84586 | 14820 | 48263 |
| $f_{3}^{*}$ | 0.141 s | 2592 | 7786 | 2469 | 6995 |
| $f_{4}^{*}$ | 0.063 s | 2597 | 7946 | 688 | 7092 |

Table 6.4: Running times, variables and constraints.

|  | $f_{1}^{*}$ | $f_{2}^{*}$ | $f_{3}^{*}$ | $f_{4}^{*}$ |
| :--- | :--- | :--- | :--- | :--- |
| $f_{1}$ | 1388.65 | 1464.01 | 1523.2 | 3187.59 |
| $f_{2}$ | 2085.93 | 2034.77 | 2096.37 | 3797.96 |
| $f_{3}$ | 232 | 237 | 189 | 318 |
| $f_{4}$ | 5 | 4 | 4 | 3 |

Table 6.5: Comparison of values for the objective functions.

|  | $f_{1}^{*}$ | $f_{2}^{*}$ | $f_{3}^{*}$ | $f_{4}^{*}$ |
| :--- | :--- | :--- | :--- | :--- |
| LP optimum | 1388.65 | 1987.3 | 186 | 2 |
| IP optimum | 1388.65 | 2034.77 | 189 | 3 |

Table 6.6: Comparison of values between the original problem and its LP relaxation.

Again we see that the LP and IP solutions coincide for $f_{1}$, but in contrast to A, the solutions are not the same for $f_{3}$. Also from table 6.2 we see that the values are the same for $f_{4}$ as the corresponding values in A .

### 6.3 Timetable C

Timetable C is longer than the previous two, and encompasses both timetable $\mathrm{A}, \mathrm{B}$ and more trains.

|  | Time | Variables | Constraints | Variables* | Constraints* |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $f_{1}^{*}$ | 0.14 s | 6723 | 12831 | 1555 | 11580 |
| $f_{2}^{*}$ | 153.125 s | 178948 | 529506 | 93220 | 279591 |
| $f_{3}^{*}$ | 0.219 s | 6723 | 12831 | 6422 | 11580 |
| $f_{4}^{*}$ | 0.25 s | 6728 | 13246 | 1559 | 11822 |

Table 6.7: Running times, variables and constraints.

|  | $f_{1}^{*}$ | $f_{2}^{*}$ | $f_{3}^{*}$ | $f_{4}^{*}$ |
| :--- | :--- | :--- | :--- | :--- |
| $f_{1}$ | 4463.48 | 4676.78 | 4854.09 | 9295.75 |
| $f_{2}$ | 6123.39 | 5976.67 | 6230.95 | 10824.9 |
| $f_{3}$ | 623 | 581 | 490 | 783 |
| $f_{4}$ | 5 | 4 | 4 | 3 |

Table 6.8: Comparison of values for the objective functions.

|  | $f_{1}^{*}$ | $f_{2}^{*}$ | $f_{3}^{*}$ | $f_{4}^{*}$ |
| :--- | :--- | :--- | :--- | :--- |
| LP optimum | 4463.48 | 5927.8 | 487 | 2 |
| IP optimum | 4463.48 | 5976.67 | 490 | 3 |

Table 6.9: Comparison of values between the original problem and its LP relaxation.

Figure 6.1: Each graph compares the value of one of the objective functions 1-3 (The blue staples) with the numbers of platforms used ( $f_{4}$, the orange lines). Each staple represents optimizing for that objective function.

As we see in figure 6.1 the solutions we get from optimizing for $f_{1}-f_{3}$ are somewhat similar, while optimizing for $f_{4}$ gives much worse solutions in terms of $f_{1}-f_{3}$. Once again the solution for the LP relaxed problem is integer for $f_{1}$. We note that even for this larger dataset that the gap between the LP and IP solution seems to be quite small for all objective functions. If this is always the case, the LP solution can be used as a good upper bound on the IP objective function.

### 6.4 Timetable D

Timetable D takes the whole day into account, starting from midnight. As previously mentioned this is the longest time horizon that is interesting to optimize for due to the train traffic being sparse during the night.

|  | Time | Variables | Constraints | Variables* | Constraints* |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $f_{1}^{*}$ | 0.266 s | 21303 | 39029 | 5644 | 36079 |
| $f_{2}^{*}$ | 5439 s | 1750530 | 5226700 | 953296 | 2818750 |
| $f_{3}^{*}$ | 0.312 s | 21303 | 39029 | 20421 | 36079 |
| $f_{4}^{*}$ | 0.156 s | 21308 | 40344 | 5648 | 36843 |

Table 6.10: Running times, variables and constraints.

|  | $f_{1}^{*}$ | $f_{2}^{*}$ | $f_{3}^{*}$ | $f_{4}^{*}$ |
| :--- | :--- | :--- | :--- | :--- |
| $f_{1}$ | 13762.2 | 13945.4 | 14750.6 | 24410.3 |
| $f_{2}$ | 18596 | 18274 | 18653.3 | 29251.6 |
| $f_{3}$ | 1911 | 1752 | 1503 | 2386 |
| $f_{4}$ | 5 | 4 | 4 | 4 |

Table 6.11: Comparison of values for the objective functions.

|  | $f_{1}^{*}$ | $f_{2}^{*}$ | $f_{3}^{*}$ | $f_{4}^{*}$ |
| :--- | :--- | :--- | :--- | :--- |
| LP optimum | 13762.2 | 18066.7 | 1503 | 2 |
| IP optimum | 13762.2 | 18274 | 1503 | 4 |

Table 6.12: Comparison of values between the original problem and its LP relaxation.

Again we note that $f_{1}$ and $f_{3}$ is integral. It is also noteworthy that large number of variables when optimizing for $f_{2}$, which yielded the very long solve time.

### 6.5 Sensitivity analysis

We have this far seen that when optimizing for minimal walking distance that we get very similar results as when optimizing for proximity to station entrance and exit. This might be due to the fact that the fraction of passengers that switch from one train to another is not big enough to affect the assignments.

To study this we study five different scenarios, where $5 \%, 10 \%, 15 \%, 20 \%$ and $25 \%$ of maximum passengers are switching between train. Just as in the results above, the trains are assumed to always run at half of maximal passenger capacity. All these five scenarios are implemented for timetable C. The results can be found in table 6.13 and seen in figure 6.2. We see that the solutions

|  | $f_{1}^{*}$ | $f_{2}^{*}$ |
| :--- | :--- | :--- |
| $\mathbf{5 \%}$ |  |  |
| $f_{1}$ | 5274.49 | 5381.14 |
| $f_{2}$ | 6104.45 | 6031.09 |
| $\mathbf{1 0 \%}$ |  |  |
| $f_{1}$ | 4463.48 | 4676.78 |
| $f_{2}$ | 6123.39 | 5976.67 |
| $\mathbf{1 5 \%}$ |  |  |
| $f_{1}$ | 3652.47 | 3972.42 |
| $f_{2}$ | 6142.34 | 5922.26 |

|  | $f_{1}^{*}$ | $f_{2}^{*}$ |
| :--- | :--- | :--- |
| $\mathbf{2 0 \%}$ |  |  |
| $f_{1}$ | 2841.46 | 3268.06 |
| $f_{2}$ | 6161.28 | 5867.84 |
| $\mathbf{2 5 \%}$ |  |  |
| $f_{1}$ | 2030.45 | 2764.88 |
| $f_{2}$ | 6180.23 | 5795.4 |

Table 6.13: The comparison of objective functions $f_{1}$ and $f_{2}$ for different levels of passengers that are switching from one train to another.
become less similar when the number of transiting passengers increases, but in general remain somewhat close (note that the axis in figure 6.2 does not start on 0 ).

### 6.6 Discussion

For the four timetables we implemented and for Linköping station there where some patterns and tendencies in the optimal solutions, and values for the objective functions.

Figure 6.2: The walking distance for the five different scenarios. The blue staples when optimizing for distance to station, the orange staples when optimizing for walking distance.

Firstly we note that $f_{1_{L P}}^{*}=f_{1_{I P}}^{*}$ for all of the four runs. It is not however the case that the constraint matrix is unimodular since the constraint matrix is the same for $f_{3}$, where $f_{3_{L P}}^{*} \neq f_{3_{I P}}^{*}$. These four results are not sufficient to show that the LP-relaxation is always integral, it might be the case four some other timetable or station that $f_{1_{L P}}^{*} \neq f_{1_{I P}}^{*}$.

From the sensitivity analysis in section 6.5 we note that the solutions for $f_{1}^{*}$ and $f_{2}^{*}$ were quite similar, even if a large fraction passengers switch trains. Under the assumption that most passengers does not switch trains, then we can use the objective function $f_{1}$, which is faster than $f_{2}$ to optimize for.

We see that the introduction of the canonical linearisation to model the function $f_{2}$ increases the complexity of the problem, and hence the solve time. This was most notable for the larger data sets.

In an earlier phase of the thesis a fifth objective function was considered. The quantity we sought to model was the number of crossing paths. By introduction of the three canonical linearisations $\lambda_{t, r, t^{\prime}, r^{\prime}}=y_{t, r} y_{t^{\prime}, r^{\prime}}, \mu_{t, r, t^{\prime}, r^{\prime}}=z_{t, r} z_{t^{\prime}, r^{\prime}}$ and $\nu_{t, r, t^{\prime}, r^{\prime}}=y_{t, r} z_{t^{\prime}, r^{\prime}}$, along with each new variables we introduced three sets of constraints similar to 4.15, 4.16 and 4.17. This gave the objective function

$$
\begin{equation*}
f_{5}(\lambda, \mu, \nu)=\sum_{t \in \mathcal{T}} \sum_{t^{\prime} \in \mathcal{T}} \sum_{r \in \mathcal{R}} \sum_{r^{\prime} \in \mathcal{R}} a_{r, r^{\prime}}\left(\frac{\lambda_{t, r, t^{\prime}, r^{\prime}}}{\left|\tau_{t}^{a}-\tau_{t^{\prime}}^{a}\right|}+\frac{\mu_{t, r, t^{\prime}, r^{\prime}}}{\left|\tau_{t}^{d}-\tau_{t^{\prime}}^{d}\right|}+\frac{\nu_{t, r, t^{\prime}, r^{\prime}}}{\left|\tau_{t}^{a}-\tau_{t^{\prime}}^{d}\right|}\right) \tag{6.1}
\end{equation*}
$$

This however proved immensely impractical. Solving for the optimal value of $f_{5}$ for the small timetable A resulted in around 1.8 million variables, and 5 million constraints after the presolve. The objective value could not be found after running the program for around 10 hours.

In conclusion we see that the introduction of one canonical linearisation is doable but significantly increases the number of variables and constraints, and therefore the running time. Using more than that in this context results in a program that is impossible to solve in a reasonable time frame, even for timetables that span a short timespan.

We also note that when optimizing for $f_{3}$ we got quite similar solutions as to those that optimize for $f_{2}$ and $f_{1}$. This is probably a result of the station layout at Linköping station. The routes through the stations that passes through the fewest switches is also the routes that stops closest to the station exit. Implementation for a station with different layout might not have this similarity.

## Chapter 7

## Conclusion

In this thesis we have presented an ILP-model to model viable assignments of trains to platforms and routes through a railway station. The model is shown to be compatible with at least four different objective functions to model for example walking distance or the number of platforms used.

To validate the model we presented an implementation for Linköping station for four different timetables. The running times for all these implementations was quick enough to be feasible to use, with exception for $f_{2}$ for the largest timetable. The solutions when optimizing for $f_{3}$ was quite close to the solution when optimizing for $f_{1}$ or $f_{2}$, which is probably due to the tracks closest to the station exit also being the tracks that passes through the least number of switches. This property is not universal, for example Norrköping central station does not have this property.

Before an optimization model similar to the one presented in this paper is used for train platforming there are several aspects that needs to be added to the model, but these results indicate that this type of model could be used to efficiently solve the TPP for at least small to medium sized stations.

It's possible that this model would work for larger stations, although this is not investigated in this thesis.

There seems to be a trade-off between the first three objective functions and number of platforms used. This might be due to the layout of Linköping station, to investigate this further implementation for other stations is needed.

The objective function $f_{2}$ had the longest running time, but we have seen that optimizing for $f_{1}$ gives a similar solution, assuming that most passengers doesn't switch to another train. Under the right conditions we could optimize for $f_{1}$ and get a solutions with good total walking distance.

### 7.1 Further research

In it's current form the model does not take into account trains that only pass through the station. This can be implemented as a train that arrives and departs at the same time from the platforms, but since these trains does not need to slow down they will reserve the track longer than necessary.

There is also need for more testing to validate the model. The model needs to be tested on larger stations to see if the running times are feasible. Furthermore the model also needs to be tested on stations with different features than Linköping, such as platforms that lie one after another on a single track, or tracks that terminate.

Depending on the results of the testing on different stations it could be interesting to modify the model to work at all stations. Little considerations were made when designing the model for computational efficiency, and it's not improbable that there are possible improvements in that regard.

Furthermore we have seen that in some instances that the LP-relaxation of the problem produces solutions that are very close to the IP solution. It would therefore be of interest to see if the model could be modified so that the LP optimal is always the IP optimal. If such a modification could be made, then it might be possible to save a some computation time, especially in the case of $f_{2}$ where the time difference for solving the LP and IP was significant. For reference the solve time for $f_{2}$ and timetable D was 5439s and the corresponding LP problem could be solved in 39s.

An approach that would be interesting to investigate is multi objective optimization, or weighted sums of objective functions. In reality we are almost never interested in minimizing just one property, but are instead interested in solutions that are "good" in all or most regards.

## Upphovsrätt

Detta dokument hålls tillgängligt på Internet - eller dess framtida ersättare från publiceringsdatum under förutsättning att inga extraordinära omständigheter uppstår.

Tillgång till dokumentet innebär tillstånd för var och en att läsa, ladda ner, skriva ut enstaka kopior för enskilt bruk och att använda det oförändrat för ickekommersiell forskning och för undervisning. Överföring av upphovsrätten vid en senare tidpunkt kan inte upphäva detta tillstånd. All annan användning av dokumentet kräver upphovsmannens medgivande. För att garantera äktheten, säkerheten och tillgängligheten finns lösningar av teknisk och administrativ art.

Upphovsmannens ideella rätt innefattar rätt att bli nämnd som upphovsman i den omfattning som god sed kräver vid användning av dokumentet på ovan beskrivna sätt samt skydd mot att dokumentet ändras eller presenteras i sådan form eller i sådant sammanhang som är kränkande för upphovsmannens litterära eller konstnärliga anseende eller egenart.
