Abstract

A stable and conservative high order multi-block method for the time-dependent compressible Navier-Stokes equations has been developed. Stability and conservation are proved using summation-by-parts operators, weak interface conditions and the energy method. This development makes it possible to exploit the efficiency of the high order finite difference method for non-trivial geometries. The computational results corroborate the theoretical analysis.

Key words: Navier-Stokes, finite difference, high order, stability, conservation

Preprint submitted to Elsevier 9 September 2009
1 Introduction

The high order finite difference method in combination with summation-by-parts operators and weak boundary conditions can very efficiently and reliably handle large problems on structured grids for reasonably smooth geometries. This has been shown in a sequence of papers, see for example [12, 24, 3, 15, 16, 18, 26, 28]. The most recent papers ([26], [28]) on this subject discuss the specific problem with far-field and no-slip boundaries. In this paper we will continue the development by treating the similar but not identical problem with a stable and accurate coupling of blocks.

In [4], [23], [29] the conventional (non-overlapping meshes) multi-block methodology is presented and discussed, but no theoretical analysis is performed. The stability of the non-overlapping multi-block techniques is analyzed in [5], [14], [6] using the one-dimensional normal mode analysis (see [10]). The overlapping grid technique has been studied in a similar manner using normal mode analysis in [2], [21], [22]. The analysis in the papers above is essentially one-dimensional (although a periodic behavior in the tangential direction can be included).

Due to the limitations of the normal mode analysis for multi-dimensional problems we will use the energy method in combination with summation-by-parts operators and weak boundary conditions as our theoretical tools. The technology in the two papers [26], [28] together with the interface treatment in this paper will conclude the development of a high order accurate and truly stable multi-block finite difference method for the Navier-Stokes equations.

In the next phase of this development we will use the coupling technique developed in this paper and combine the high order finite difference method with the finite volume method in combination with unstructured grids which can more readily handle complex geometries. That development is ongoing, see for example [17], [7] and [19]. The development in this paper is the theoretical foundation for that work.

The main challenge for multi-block methods is to control the possible instability at the block interfaces between sub-domains. We will focus on that problem and for the first time prove stability and conservation of a high order accurate multi-block finite difference method applied to the Navier-Stokes equations. The analysis will be done for the linear constant coefficient Navier-Stokes equations. The theoretical development is validated in numerical computations where the full non-linear Navier-Stokes equations are used.

The rest of the paper is organized as follows. In the next section we present the symmetric constant coefficient form of the Navier-Stokes equations followed by a short discussion of well-posedness in section 3. The formulation of the
numerical method on a single domain is considered in section 4. The coupling
procedure is the topic of section 5 and the numerical experiments are presented
in section 6. Finally, conclusions are drawn in section 7.

2 The Navier-Stokes equations

The frozen coefficient time-dependent compressible Navier-Stokes equations
in two-dimensions in non-conservative form are given by, see [1]

\[ \ddot{u}_t + A\ddot{u}_x + B\ddot{u}_y = C\ddot{u}_{xx} + D\ddot{u}_{xy} + E\ddot{u}_{xy}, \]  

(1)

where \( \ddot{u} = [\ddot{\rho}, \ddot{u}_1, \ddot{u}_2, \ddot{p}]^T \) and \( A, B, C, D, \) and \( E \) are coefficient matrices. \( \ddot{\rho} \) is the
density, \( \ddot{u}_1 \) and \( \ddot{u}_2 \) are the velocities and \( \ddot{p} \) is the pressure. The coefficients are
frozen at the constant state \( u = [\rho, u_1, u_2, p]^T \). To apply the energy method
we must symmetrize (1). The procedure developed in [1] and [20] yield a
symmetric form of (1),

\[ u_t + (A_1u)_x + (A_2u)_y = \varepsilon \left[ (B_{11}u_x + B_{12}u_y)_x + (B_{21}u_x + B_{22}u_y)_y \right], \]  

(2)

with \( \varepsilon = 1/Re, u = (c\ddot{\rho}/(\sqrt{\gamma p}), \ddot{u}_1, \ddot{u}_2, \ddot{p}\ddot{T}/\sqrt{\gamma(\gamma - 1)})^T \) and

\[
A_1 = \begin{bmatrix}
  u_1 & \frac{c}{\sqrt{\gamma}} & 0 & 0 \\
  \frac{c}{\sqrt{\gamma}} & u_1 & 0 & \sqrt{\frac{\gamma - 1}{\gamma}} c \\
  0 & 0 & u_1 & 0 \\
  0 & \sqrt{\frac{\gamma - 1}{\gamma}} c & 0 & u_1 \\
\end{bmatrix}, \quad A_2 = \begin{bmatrix}
  u_2 & 0 & \frac{c}{\sqrt{\gamma}} & 0 \\
  0 & u_2 & 0 & 0 \\
  \frac{c}{\sqrt{\gamma}} & 0 & u_2 & \sqrt{\frac{\gamma - 1}{\gamma}} c \\
  0 & 0 & \sqrt{\frac{\gamma - 1}{\gamma}} c & u_2 \\
\end{bmatrix},
\]

\[
B_{11} = \begin{bmatrix}
  0 & 0 & 0 & 0 \\
  0 & \frac{\lambda + 2\mu}{\rho} & 0 & 0 \\
  0 & 0 & \frac{\mu}{\rho} & 0 \\
  0 & 0 & 0 & \frac{\gamma\mu}{Pr\rho} \\
\end{bmatrix}, \quad B_{12} = B_{21} = \begin{bmatrix}
  0 & 0 & 0 & 0 \\
  0 & 0 & \frac{\lambda + \mu}{2\rho} & 0 \\
  0 & \frac{\mu}{\rho} & 0 & 0 \\
  0 & 0 & 0 & 0 \\
\end{bmatrix}, \quad B_{22} = \begin{bmatrix}
  0 & 0 & 0 & 0 \\
  0 & \frac{\lambda + 2\mu}{\rho} & 0 & 0 \\
  0 & 0 & \rho & 0 \\
  0 & 0 & 0 & \frac{\gamma\mu}{Pr\rho} \\
\end{bmatrix}.
\]

In the vectors and matrices above we have used the temperature \( \ddot{T} \), the ratio
of the specific heats \( \gamma = c_p/c_v \), the speed of sound \( c \), the dynamic viscosity
\( \mu \), the bulk viscosity \( \lambda \), the kinematic viscosity \( \nu = \mu/\rho \), the Prandtl number
\( Pr = \nu/\alpha \) (\( \alpha \) is the thermal diffusivity) and the Reynolds number \( Re = \rho_\infty U_\infty L/\mu_\infty \). The infinity subscript denotes free stream conditions and \( L \) is
a characteristic length. Note again that the form of the matrices (Jacobians)
above are obtained for the symmetrized frozen coefficient version of the Navier-Stokes equations.

Equation (2) can be rewritten in conservative form as

\[ u_t + F_x + G_y = 0, \]  

(3)

where

\[ F = A_1 u - \varepsilon (B_{11} u_x + B_{12} u_y) = F^I - \varepsilon F^V, \]

\[ G = A_2 u - \varepsilon (B_{21} u_x + B_{22} u_y) = G^I - \varepsilon G^V. \]  

(4)

\( F^I \) and \( G^I \) contain the inviscid terms and \( F^V \) and \( G^V \) the viscous terms.

3 Well-posedness of the continuous problem

To keep the algebraic complexity of the analysis as low as possible, we consider rectangular domains with cartesian coordinates. Applying the energy method to (3) on the domain \( \Omega \in [-1, 1] \times [0, 1] \) we obtain

\[ \int_{\Omega} u^T u_t dxdy + \int_{\Omega} u^T F_x dxdy + \int_{\Omega} u^T G_y dxdy = 0. \]  

(5)

By using the Green-Gauss theorem, equation (5) can be written as

\[ \frac{d}{dt}(\|u\|^2) = -\left[ \int_{-1}^{1} u_t^T (F^I - 2\varepsilon F^V) \bigg|_{x=1}^y - \int_{0}^{1} u_t^T (F^I - 2\varepsilon F^V) \bigg|_{x=-1}^y \right] \]

\[ -\left[ \int_{-1}^{1} u^T (G^I - 2\varepsilon G^V) \bigg|_{y=0}^x dx - \int_{0}^{-1} u^T (G^I - 2\varepsilon G^V) \bigg|_{y=1}^x dx \right] \]

\[ -2\varepsilon \int_{\Omega} \begin{bmatrix} u_x \\ u_y \end{bmatrix}^T \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{bmatrix} u_x \\ u_y \end{bmatrix} dx dy. \]  

(6)

To have a bounded energy growth, the boundary terms (East, West, North and South) must be bounded using the correct number and form of boundary conditions. That is the topic in papers [26],[28] and it is not discussed further here. The contribution from the integral term is negative semi-definite since the matrix \( B = [B_{11} \ B_{12}; B_{21} \ B_{22}] \) is positive semi-definite.

We summarize the result for the continuous problem (2)-(4) in the following proposition.
Proposition 3.1 The continuous problem (2)-(4) is well posed if the boundary terms are limited by using the correct number of the boundary conditions.

Remark The \( n \)-dimensional Navier-Stokes equations require \( n \) boundary conditions at an inflow boundary and \( n-1 \) at an outflow boundary. In this case (two-dimensions) we need four boundary conditions an inflow boundary and three at an outflow boundary, see for example [25],[10],[20].

4 Stability on a single domain

Consider the computational domain with a Cartesian mesh of \((M+1) \times (N+1)\) points. Let the \( k \)-th element of the continuous variable \( u \) at the structured grid point \((x_i, y_j)\) be \( u(i,j,k) \) \((0 \leq k \leq 3)\). The finite difference approximation of \( u(i,j,k) \) is collected in a global vector \( v \) such that
\[
 v[4i(N+1) + 4j + k] = u(i,j,k) \quad (0 \leq i \leq M, 0 \leq j \leq N \text{ and } 0 \leq k \leq 3).
\]
Let \( v_x \) and \( v_y \) be approximations of \( u_x \) and \( u_y \).

By using the finite difference method developed in [12,24,3,15,16,18,26,28] a semi-discrete approximation of equation (3) can be written as
\[
 v_t + D_x F + D_y G = 0 \quad (7)
\]
where \( D_x = P_x^{-1}Q_x \otimes I_y \otimes I_4 \) and \( D_y = I_x \otimes P_y^{-1}Q_y \otimes I_4 \) are first derivative operators in \( x \)-, and \( y \)-directions, respectively. \( I_x \) and \( I_y \) are the identity matrices of size \((M+1) \times (M+1)\) and \((N+1) \times (N+1)\). Moreover,
\[
 F = F^I - \varepsilon F^V, \quad G = G^I - \varepsilon G^V \\
 F^I = (I_x \otimes I_y \otimes A_1)v, \quad F^V = (I_x \otimes I_y \otimes B_{11})v_x + (I_x \otimes I_y \otimes B_{12})v_y, \\
 G^I = (I_x \otimes I_y \otimes A_2)v, \quad G^V = (I_x \otimes I_y \otimes B_{21})v_x + (I_x \otimes I_y \otimes B_{22})v_y,
\]
and \( v_x = D_x v, v_y = D_y v \). Let \( \bar{P} = P_x \otimes P_y \) and multiply equation (7) with \( v^T(\bar{P} \otimes I_4) \). (This is the discrete equivalent of multiplying (3) with \( v^T \) and integrating over the computational domain to get the energy estimate (6)).

This leads to
\[
 v^T(\bar{P} \otimes I_4)v_t + v^T(Q_x \otimes P_y \otimes I_4)F + v^T(P_x \otimes Q_y \otimes I_4)G = 0 \quad (8)
\]
By adding the transpose of equation (8) to itself and using the SBP relations
\[
 Q_x + Q_x^T = \text{diag}(-1,0,\ldots,0,1), \quad Q_y + Q_y^T = \text{diag}(-1,0,\ldots,0,1) \quad (9)
\]
we can write the result as
\[
\frac{d}{dt} \left( \| \mathbf{v} \|^2_{P \otimes I_4} \right) = -\mathbf{v}^T \mathbf{v} + \varepsilon \mathbf{v}^T \mathbf{v}. \tag{10}
\]

The inviscid term IT in (10) is
\[
IT = \mathbf{v}^T (Q_x \otimes P_y \otimes I_4) \mathbf{F}^I + (\mathbf{F}^I)^T (Q_x^T \otimes P_y \otimes I_4) \mathbf{v} + \\
\mathbf{v}^T (P_x \otimes Q_y \otimes I_4) \mathbf{G}^I + (\mathbf{G}^I)^T (P_x \otimes Q_y^T \otimes I_4) \mathbf{v} \\
= \underbrace{\mathbf{v}_E^T (P_y \otimes I_4) \mathbf{F}_E^I}_\text{East} - \underbrace{\mathbf{v}_W^T (P_y \otimes I_4) \mathbf{F}_W^I}_\text{West} - \underbrace{\mathbf{v}_S^T (P_x \otimes I_4) \mathbf{G}_S^I}_\text{South} + \underbrace{\mathbf{v}_N^T (P_x \otimes I_4) \mathbf{G}_N^I}_\text{North} \tag{11}
\]

The viscous term VT in (10) can be written as
\[
VT = \mathbf{v}^T (Q_x \otimes P_y \otimes I_4) \mathbf{F}^V + (\mathbf{F}^V)^T (Q_x^T \otimes P_y \otimes I_4) \mathbf{v} + \\
\mathbf{v}^T (P_x \otimes Q_y \otimes I_4) \mathbf{G}^V + (\mathbf{G}^V)^T (P_x \otimes Q_y^T \otimes I_4) \mathbf{v} \\
= 2 \underbrace{\mathbf{v}_E^T (P_y \otimes I_4) \mathbf{F}_E^V}_\text{East} - 2 \underbrace{\mathbf{v}_W^T (P_y \otimes I_4) \mathbf{F}_W^V}_\text{West} - 2 \underbrace{\mathbf{v}_S^T (P_x \otimes I_4) \mathbf{G}_S^V}_\text{South} \\
+ 2 \mathbf{v}_N^T (P_x \otimes I_4) \mathbf{G}_N^V \tag{12}
\]

An expanded version of equation (10) using the relations above becomes
\[
\frac{d}{dt} \left( \| \mathbf{v} \|^2_{P \otimes I_4} \right) = - \underbrace{\mathbf{v}_E^T (P_y \otimes I_4) \mathbf{F}_E^I - 2\varepsilon \mathbf{F}_E^V}_{\text{East}} + \underbrace{\mathbf{v}_W^T (P_y \otimes I_4) \mathbf{F}_W^I - 2\varepsilon \mathbf{F}_W^V}_{\text{West}} \\
+ \underbrace{\mathbf{v}_S^T (P_x \otimes I_4) \mathbf{G}_S^I - 2\varepsilon \mathbf{G}_S^V}_{\text{South}} - \underbrace{\mathbf{v}_N^T (P_x \otimes I_4) \mathbf{G}_N^I - 2\varepsilon \mathbf{G}_N^V}_{\text{North}} \\
- 2\varepsilon \begin{bmatrix} \mathbf{v}_x^T \\ \mathbf{v}_y^T \end{bmatrix} ^\mathsf{T} \begin{bmatrix} \mathbf{P} \otimes B_{11} & \mathbf{P} \otimes B_{12} \\ \bar{\mathbf{P}} \otimes B_{21} & \bar{\mathbf{P}} \otimes B_{22} \end{bmatrix} \begin{bmatrix} \mathbf{v}_x \\ \mathbf{v}_y \end{bmatrix}. \tag{13}
\]

Note that for square matrices \( \mathbf{P} \) and \( B_{11} \) (or \( B_{12}, B_{21} \) and \( B_{22} \)) the Kronecker product \( \mathbf{P} \otimes B_{11} \) and \( B_{11} \otimes \mathbf{P} \) are even permutation similar, that is, there exists a permutation matrix \( \Phi \) such that \( \mathbf{P} \otimes B_{11} = \Phi^T (B_{11} \otimes \mathbf{P}) \Phi \), see [11] for details. Equation (13) can therefore be written
\[
\frac{d}{dt} \left( \| \mathbf{v} \|^2_{P \otimes I_4} \right) = \mathbf{B} \mathbf{T} - 2\varepsilon \begin{bmatrix} \mathbf{w}_x^T \\ \mathbf{w}_y^T \end{bmatrix} ^\mathsf{T} \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \otimes \bar{\mathbf{P}} \begin{bmatrix} \mathbf{w}_x \\ \mathbf{w}_y \end{bmatrix}. \tag{14}
\]
where BT collect all the boundary terms in (13) and $w_x = \Phi v_x, w_y = \Phi v_y$.

Exactly similar to the continuous case, a bounded energy growth in (14) require boundedness in terms of given data of the boundary terms (East, West, North and South). Again, that is dealt with in the papers [26],[28] where the boundary conditions are implemented using penalty terms. The contribution from the quadratic form in (14) is negative semi-definite since the matrix $\bar{P}$ is positive definite and $B = [B_{11}, B_{12}; B_{21}, B_{22}]$ is positive semi-definite.

Exactly similar to the continuous case, we summarize the result for the semi-discrete single domain problem (7) in the following proposition.

**Proposition 4.1** The semi-discrete problem (7) is stable if the boundary terms are limited by appropriate boundary procedures.

### 5 Stable and conservative interface conditions

We consider a computational domain consisting of two sub-domains and a common interface at $x = 0$, see Figure 1. Let $u$ and $v$ be the unknowns in the left and right sub-domain, respectively, and introduce the superscripts $L$ and $R$ to identify the left and right sub-domains.

The semi-discrete approximation of (2) on the two sub-domains with an interface can be written

$$u_t + D_x^L F^L + D_y^L G^L = (M^L)^{-1} \left( \sum_i^L [u_i - v_i] + \sum_i^L [(F^V)_i^L - (F^V)_i^R] \right), \tag{15a}$$

$$v_t + D_x^R F^R + D_y^R G^R = (M^R)^{-1} \left( \sum_i^R [v_i - u_i] + \sum_i^R [(F^V)_i^R - (F^V)_i^L] \right), \tag{15b}$$
where the matrices $E^{L}$, $E^{R}$ picks out the parts of the vectors residing at the interface such that for example $u_i = E^{L} u$, $v_i = E^{R} v$. In the following, the subscript $i$ indicates that the quantity resides on the interface. We also have the definitions:

\[ D_{x}^{L} = (P_{x}^{L})^{-1} Q_{x}^{L} \otimes I_{y}^{L} \otimes I_{4}, \quad D_{y}^{L} = I_{x}^{L} \otimes (P_{y}^{L})^{-1} Q_{y}^{L} \otimes I_{4}, \]
\[ D_{x}^{R} = (P_{x}^{R})^{-1} Q_{x}^{R} \otimes I_{y}^{R} \otimes I_{4}, \quad D_{y}^{R} = I_{x}^{R} \otimes (P_{y}^{R})^{-1} Q_{y}^{R} \otimes I_{4}, \]
\[ M^{L} = P_{x}^{L} \otimes P_{y}^{L} \otimes I_{4}, \quad M^{R} = P_{x}^{R} \otimes P_{y}^{R} \otimes I_{4}, \]
\[ \Sigma_{1}^{L} = (E^{L})^{T} P_{y}^{L} \otimes \Sigma_{1}^{L}, \quad \Sigma_{2}^{L} = (E^{L})^{T} P_{y}^{L} \otimes \Sigma_{2}^{L}, \]
\[ \Sigma_{1}^{R} = (E^{R})^{T} P_{y}^{R} \otimes \Sigma_{1}^{R}, \quad \Sigma_{2}^{R} = (E^{R})^{T} P_{y}^{R} \otimes \Sigma_{2}^{R}. \] (16)

The definitions of $F$ and $G$ are given in section 4 above and $\Sigma_{1}^{L}, \Sigma_{1}^{R}, \Sigma_{2}^{L}, \Sigma_{2}^{R}$ unknown penalty matrices. Note that the outer boundary conditions are neglected in this analysis, for separate treatment of these see [26],[28].

We will determine the penalty matrices $\Sigma_{1}^{L}, \Sigma_{1}^{R}, \Sigma_{2}^{L}, \Sigma_{2}^{R}$ by stability and conservation requirements (see [3,15,16,18] for previous applications of this technique). Applying the energy method to (15a) and (15b) yields

\[ \frac{d}{dt} \left( ||u||_{M^{L}}^2 + ||v||_{M^{R}}^2 \right) + 2\varepsilon \text{Diss} = w_{i}^{T} M w_{i} \] (17)

where

\[ w_{i} = [u_{i}, v_{i}, (u_{x})_{i}, (v_{x})_{i}, (u_{y})_{i}, (v_{y})_{i}]^{T} \]

and

\[ \text{Diss} = \begin{bmatrix} u_{x}^{T} \\ u_{y}^{T} \\ v_{x}^{T} \\ v_{y}^{T} \end{bmatrix} \begin{bmatrix} P_{x}^{L} \otimes P_{y}^{L} \otimes B_{11} & P_{x}^{L} \otimes P_{y}^{L} \otimes B_{12} \\ P_{x}^{L} \otimes P_{y}^{L} \otimes B_{21} & P_{x}^{L} \otimes P_{y}^{L} \otimes B_{22} \\ P_{x}^{R} \otimes P_{y}^{R} \otimes B_{11} & P_{x}^{R} \otimes P_{y}^{R} \otimes B_{12} \\ P_{x}^{R} \otimes P_{y}^{R} \otimes B_{21} & P_{x}^{R} \otimes P_{y}^{R} \otimes B_{22} \end{bmatrix} \begin{bmatrix} u_{x} \\ u_{y} \\ v_{x} \\ v_{y} \end{bmatrix} + \]

\[ \sum_{i=1}^{6} M_{ii} = P_{y}^{L} \otimes (-A_{i} + \Sigma_{1}^{L} + (\Sigma_{1}^{L})^{T}), \quad M_{12} = P_{y}^{L} \otimes \Sigma_{2}^{L} + P_{y}^{R} \otimes (\Sigma_{1}^{R})^{T}, \]
\[ M_{13} = P_{y}^{L} \otimes (\varepsilon I_{4} + \Sigma_{2}^{L}) B_{11}, \quad M_{14} = P_{y}^{L} \otimes -\Sigma_{2}^{L} B_{11}, \]
\[ M_{15} = P_{y}^{L} \otimes (\varepsilon I_{4} + \Sigma_{2}^{L}) B_{12}, \quad M_{16} = P_{y}^{L} \otimes -\Sigma_{2}^{L} B_{12}, \]
\[ M_{22} = P_{y}^{R} \otimes (A_{i} + \Sigma_{1}^{R} + (\Sigma_{1}^{R})^{T}), \quad M_{23} = P_{y}^{R} \otimes -\Sigma_{2}^{R} B_{11}, \]
\[ M_{24} = P_{y}^{R} \otimes (\varepsilon I_{4} + \Sigma_{2}^{R}) B_{11}, \quad M_{25} = P_{y}^{R} \otimes +\Sigma_{2}^{R} B_{12}, \]
\[ M_{26} = P_{y}^{R} \otimes (\varepsilon I_{4} + \Sigma_{2}^{R}) B_{12}, \quad M_{33} = M_{34} = M_{35} = M_{36} = 0, \]
\[ M_{44} = M_{45} = M_{46} = 0, \quad M_{55} = M_{56} = M_{66} = 0. \]

Notice that the matrix $M$ in its present form is indefinite.

In order to construct a symmetric semi-definite negative matrix on the right hand side of equation (17) we must “borrow” interface terms from Diss on the left hand
side, see [3]. The term Diss can be written as

\[ \text{Diss} = \widetilde{\text{Diss}} + \alpha^L p^L \begin{bmatrix} u_x \end{bmatrix}^T \begin{bmatrix} p^L \otimes B_{11} & p^L \otimes B_{12} \\ p^L \otimes B_{21} & p^L \otimes B_{22} \end{bmatrix} \begin{bmatrix} u_x \end{bmatrix} + \beta^R p^R \begin{bmatrix} v_x \end{bmatrix}^T \begin{bmatrix} p^R \otimes B_{11} & p^R \otimes B_{12} \\ p^R \otimes B_{21} & p^R \otimes B_{22} \end{bmatrix} \begin{bmatrix} v_x \end{bmatrix}, \]

where \( p^L = (P^L_{x})_{M,M}, p^R = (P^R_{x})_{1,1} \) and

\[ \widetilde{\text{Diss}} = \begin{bmatrix} u_x \end{bmatrix}^T \begin{bmatrix} \widetilde{P}^L_x \otimes \widetilde{P}^L_y \otimes B_{11} & \widetilde{P}^L_x \otimes \widetilde{P}^L_y \otimes B_{12} \\ \widetilde{P}^L_x \otimes \widetilde{P}^L_y \otimes B_{21} & \widetilde{P}^L_x \otimes \widetilde{P}^L_y \otimes B_{22} \end{bmatrix} \begin{bmatrix} u_x \end{bmatrix} \]

The modified norms in \( \widetilde{\text{Diss}} \) are \( \widetilde{P}^L_x = P^L_x - \text{diag}(0, \ldots, \alpha^L, 0) \) and \( \widetilde{P}^R_x = P^R_x - \text{diag}(\beta^R, 0, \ldots, 0) \). Note that with \( 0 < \alpha^L, \beta^R \leq 1 \), then \( \widetilde{P}^L_x \geq 0 \) and \( \widetilde{P}^R_x \geq 0 \) and hence \( \widetilde{\text{Diss}} \geq 0 \).

As a result, the modified version of equation (17) can be written as

\[ \frac{d}{dt} \left( \|u\|^2_{M^L} + \|v\|^2_{M^R} \right) + 2\varepsilon \widetilde{\text{Diss}} = w_i^T M \dot{w}_i, \]  

(18)

where \( \widetilde{M} \) plays the role of \( M \) except that the zero elements in \( M \) are replaced by

\[
\begin{align*}
M_{33} &= -2\varepsilon \alpha^L p^L y_t \otimes B_{11}, & M_{35} &= -2\varepsilon \alpha^L p^L y_t \otimes B_{12}, \\
M_{44} &= -2\varepsilon \beta^R r^R y_t \otimes B_{11}, & M_{46} &= -2\varepsilon \beta^R r^R y_t \otimes B_{12}, \\
M_{55} &= -2\varepsilon \alpha^L p^L y_t \otimes B_{22}, & M_{66} &= -2\varepsilon \beta^R r^R y_t \otimes 2B_{22}, \\
M_{53} &= M_{35}^T, & M_{64} &= M_{46}^T.
\end{align*}
\]

\[ 5.1 \text{ Conservation conditions} \]

Before considering the stability, we investigate the conservation properties at the interface. Let \( \varphi \) be a smooth test function with compact support, multiply equation (3) with \( \varphi \) and integrate over the spatial domain \( \Omega \in [-1, 1] \times [0, 1] \). We obtain

\[
\int_\Omega \varphi^T u_i dx dy - \int_\Omega (\varphi_x^T F + \varphi_y^T G) dx dy = 0.
\]

(19)

The conservative form of equation (3) makes it possible to use integration-by-parts and move the differentiation on to the smooth continuous function \( \varphi \).
We want to preserve this property in the discrete case. For the single domain problem this is trivial since the SBP operators are constructed to do just that, see equation (9). However, in the multi-domain case we have an interface and extra care is necessary.

With a slight abuse of notation we also let $\varphi$ denote a smooth grid function. Note that this means that $\varphi^L_i = \varphi^R_i = \varphi_i$. Multiplying equations (15a) and (15b) by $(\varphi^T M)^L$ and $(\varphi^T M)^R$ respectively and using the SBP relations (9) leads to

$$(\varphi^T M)^L u_t + (\varphi^T M)^R v_t - (\varphi_x^T M F + \varphi_y^T M G)^L - (\varphi_x^T M F + \varphi_y^T M G)^R = IT. \quad (20)$$

The $M^L, M^R$ involved in (20) are defined in (16). The left-hand side of (20) corresponds exactly to the left-hand side of (19). As usual we have neglected the outer boundary terms.

If the interface term $IT$ at the right-hand side of (20) vanish, we have a conservative scheme. The interface term is

$$IT = (P_y^L \otimes A_1) u_i + (P_y^R \otimes A_1) v_i + (P_y^L \otimes \Sigma_1^L - P_y^R \otimes \Sigma_1^R)(u_i - v_i)$$

$$(P_y^L \otimes \varepsilon I_4)(F^V)^L - (P_y^R \otimes \varepsilon I_4)(F^V)^R$$

$$(P_y^L \otimes \Sigma_1^L - P_y^R \otimes \Sigma_1^R)((F^V)^L - (F^V)^R).$$

The choice $P_y^L = P_y^R$ and the conditions (21) below cancel the interface term $IT$ in (20) and lead to a conservative scheme.

$$\Sigma_1^R = \Sigma_1^L - A_1, \quad \Sigma_2^R = \Sigma_2^L + \varepsilon I_4 \quad (21)$$

**Remark** The conservation conditions (21) are a subset of the resulting stability conditions, see also [3,15,16,18] where similar conservation conditions were derived.

**Remark** The condition $P_y^L = P_y^R$ implies that the same SBP operators should be used in the $y$-direction in both sub-domains. This restriction can be removed, and that will be the topic in a future paper.

### 5.2 Stability conditions

Inserting $P_y^L = P_y^R = P_y$ and the conservation conditions (21) into (18) results in

$$\frac{d}{dt} \left( \|u\|^2_{M^L} + \|v\|^2_{M^R} \right) + 2 \varepsilon \text{Diss} = -x^T (N \otimes P_y) x, \quad (22)$$
where

\[
\begin{bmatrix}
\Phi u \\
\Psi v \\
\Phi u_x \\
\Psi v_x \\
\Phi v_y \\
\Psi v_y
\end{bmatrix}, \quad
N = \begin{bmatrix}
N_{11} & -N_{11} & N_{13} & N_{14} & N_{15} & N_{16} \\
-N_{11} & N_{11} & -N_{13} & -N_{14} & -N_{15} & -N_{16} \\
N_{T}^T_{13} & -N_{T}^T_{13} & N_{33} & 0 & N_{35} & 0 \\
N_{T}^T_{14} & -N_{T}^T_{14} & 0 & N_{44} & 0 & N_{46} \\
N_{T}^T_{15} & -N_{T}^T_{15} & N_{T}^T_{35} & 0 & N_{55} & 0 \\
N_{T}^T_{16} & -N_{T}^T_{16} & 0 & N_{T}^T_{46} & 0 & N_{66}
\end{bmatrix}
\]

The permutation matrices \( \Phi \) and \( \Psi \) are defined in Section 4 and

\[
N_{11} = A_1 - \Sigma^L_1 - (\Sigma^L_1)^T, \quad N_{13} = -(\varepsilon I_4 + \Sigma^L_2)B_{11}, \quad N_{14} = \Sigma^L_2 B_{11},
\]

\[
N_{15} = -\varepsilon I_4 - \Sigma^L_2 B_{12}, \quad N_{16} = \Sigma^L_2 B_{12}, \quad N_{33} = 2\varepsilon \alpha L p^L B_{12},
\]

\[
N_{35} = 2\varepsilon \alpha L p^L B_{21}, \quad N_{44} = 2\varepsilon \beta R p^R B_{11}, \quad N_{46} = 2\varepsilon \beta R p^R B_{12},
\]

\[
N_{55} = 2\varepsilon \alpha L p^L B_{22}, \quad N_{66} = 2\varepsilon \beta R p^R B_{22}.
\]

A bounded energy require a positive semi-definite matrix \( N \). To simplify the algebra we introduce a transformation matrix \( S \) such that \( S^T S = I \) and

\[
S = \begin{bmatrix}
\frac{1}{\sqrt{2}} I_4 & \frac{1}{\sqrt{2}} I_4 & 0 & 0 & 0 & 0 \\
0 & 0 & I_4 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & I_4 & 0 \\
0 & 0 & 0 & I_4 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & I_4 \\
\frac{1}{\sqrt{2}} I_4 & -\frac{1}{\sqrt{2}} I_4 & 0 & 0 & 0 & 0
\end{bmatrix}, \quad
\tilde{N} = SNST = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & N_{33} & N_{35} & 0 & 0 & \sqrt{2}N_{13} \\
0 & N_{T}^T_{35} & N_{55} & 0 & 0 & \sqrt{2}N_{15} \\
0 & 0 & 0 & N_{44} & N_{46} & \sqrt{2}N_{14} \\
0 & 0 & 0 & N_{T}^T_{46} & N_{66} & \sqrt{2}N_{16} \\
0 & \sqrt{2}N_{13} & \sqrt{2}N_{15} & \sqrt{2}N_{14} & \sqrt{2}N_{16} & 2N_{11}
\end{bmatrix}
\]

To simplify the matrix \( \tilde{N} \) we introduce

\[
\alpha = \alpha L p^L, \quad \beta = \beta R p^R, \quad \Sigma^L_2 = -\varepsilon \Delta, \quad \Sigma^L_1 = \Sigma^L_1 + \varepsilon \Sigma^L_1 V,
\]

where we choose \( \Delta \) to be diagonal. The splitting and scaling with \( \varepsilon \) in (23) are made for convenience and means that \( \tilde{N} \) can be split into an inviscid part \( \tilde{N}_I \) and a viscous part \( \tilde{N}_V \) which simplifies the analysis. By making use of (23) we get

\[
\tilde{N} \approx \begin{bmatrix}
0_{4,4} & 0_{4,8} & 0_{4,8} & 0_{4,4} \\
0_{8,4} & 2\alpha K_{11} & 0_{8,8} & \sqrt{2}K_{13} \\
0_{8,4} & 0_{8,8} & 2\beta K_{11} & \sqrt{2}K_{23} \\
0_{4,4} & \sqrt{2}K_{13}^T & \sqrt{2}K_{23}^T & 2K_{33}
\end{bmatrix}
\]

where

\[
\tilde{N}_I = \begin{bmatrix}
0_{20,20} & 0_{20,4} \\
0_{4,20} & 2(A_1 - \Sigma^L_1 - (\Sigma^L_1)^T)
\end{bmatrix}/\hat{N}_I, \quad
\tilde{N}_V = \begin{bmatrix}
0_{4,4} & 0_{4,8} & 0_{4,8} & 0_{4,4} \\
0_{8,4} & 2\alpha K_{11} & 0_{8,8} & \sqrt{2}K_{13} \\
0_{8,4} & 0_{8,8} & 2\beta K_{11} & \sqrt{2}K_{23} \\
0_{4,4} & \sqrt{2}K_{13}^T & \sqrt{2}K_{23}^T & 2K_{33}
\end{bmatrix}
\]

(24)
where \( K_{33} = -(\Sigma_{1V} + (\Sigma_{1V})^T) \) and
\[
K_{11} = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix}, \quad K_{13} = \begin{bmatrix} (\Delta - I_4)B_{11} \\ (\Delta - I_4)B_{12} \end{bmatrix}, \quad K_{23} = \begin{bmatrix} -\Delta B_{11} \\ -\Delta B_{12} \end{bmatrix}.
\]
The subscripts on \( \mathbf{0} \) in (24) indicate the size of the block.

The condition for \( \tilde{N}_I \) in equation (24) to be positive semi-definite is
\[
A_1 - \Sigma^L_{1I} - (\Sigma^L_{1I})^T \geq 0.
\] (25)
If \( A_1 \) is rewritten as \( A_1 = X^T \Lambda X = X^T \Lambda^+ X + X^T \Lambda^- X = A_1^+ + A_1^- \) where \( \Lambda^+ = \text{diag}(\max(\lambda_i,0)), \, \Lambda^- = \text{diag}(\min(\lambda_i,0)) \) and \( \lambda_i \) are the eigenvalues of \( A_1 \), we find that (25) is satisfied if
\[
\Sigma^L_{1I} + (\Sigma^L_{1I})^T \leq A_1^-.
\] (26)

Next we turn to the more difficult analysis of the definiteness of \( \hat{N}_V \). The dimensions of \( \hat{N}_V \) and the matrices \( K_{11}, K_{13}, K_{23} \) and \( K_{33} \) are given in (24). Note that since the matrices \( B_{ij} \) all lack the first row and column, the only non-zero part of \( \hat{N}_V \) that we need to consider for definiteness is the condensed version (we neglect the rows and columns that consist of zeros) of the lower 3 \( \times \) 3 block in (24).

Let us denote the condensed version of the lower 3 \( \times \) 3 block in \( \hat{N}_V \) with \( \hat{N} \) and use a similar notation also for the rest of the matrices. That means that we should consider definiteness of
\[
\tilde{N} = \begin{bmatrix} 2\alpha \tilde{K}_{11} & 0_{6,6} & \sqrt{2} \tilde{K}_{13} \\ 0_{6,6} & 2\beta \tilde{K}_{11} & \sqrt{2} \tilde{K}_{23} \\ \sqrt{2} \tilde{K}_{13} & \sqrt{2} \tilde{K}_{23} & 2\tilde{K}_{33} \end{bmatrix}, \quad \tilde{K}_{33} = -(\Sigma + \Sigma^T)
\] (27)
\[
\tilde{K}_{11} = \begin{bmatrix} \tilde{B}_{11} & \tilde{B}_{12} \\ \tilde{B}_{21} & \tilde{B}_{22} \end{bmatrix}, \quad \tilde{K}_{13} = \begin{bmatrix} (\Delta - I_3)\tilde{B}_{11} \\ (\Delta - I_3)\tilde{B}_{12} \end{bmatrix}, \quad \tilde{K}_{23} = \begin{bmatrix} -\Delta \tilde{B}_{11} \\ -\Delta \tilde{B}_{12} \end{bmatrix}.
\] (28)

Note again that we have now replaced all 4 \( \times \) 4 matrices with the corresponding 3 \( \times \) 3 ones. We have also kept the notation \( \Delta \) and changed \( \Sigma_{1V} \) to \( \Sigma \).

We find that a sufficient condition for positive semi-definiteness of \( \tilde{N} \) is
\[
\tilde{K}_{11} > 0 \quad \text{and} \quad -(\Sigma + \Sigma^T) = \tilde{K}_{33} \geq \frac{1}{2\alpha} \tilde{K}_{13}^T \tilde{K}_{11}^{-1} \tilde{K}_{13} + \frac{1}{2\beta} \tilde{K}_{23}^T \tilde{K}_{33}^{-1} \tilde{K}_{23},
\] (29)
because we can factorize \( \tilde{N} \) as \( \tilde{N} = \varepsilon LDL^T \) with
\[
D = \begin{bmatrix} 2\alpha \tilde{K}_{11} & 0 & 0 \\ 0 & 2\beta \tilde{K}_{11} & 0 \\ 0 & 0 & D_{33} \end{bmatrix}, \quad L = \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ \frac{1}{\sqrt{2\alpha}} \tilde{K}_{13}^T \tilde{K}_{11}^{-1} & \frac{1}{\sqrt{2\beta}} \tilde{K}_{23}^T \tilde{K}_{33}^{-1} & I \end{bmatrix},
\] (30)
and \( D_{33} = 2 \tilde{K}_{33} - \frac{1}{\alpha} \tilde{K}^T_{13} \tilde{K}^{-1}_{11} \tilde{K}_{13} - \frac{1}{\beta} \tilde{K}^T_{23} \tilde{K}^{-1}_{11} \tilde{K}_{23} \).

The conditions (21), (25) and (29) make the matrix \( \hat{N} \) positive semi-definite, which implies that matrix \( N \) is positive semi-definite, since for an arbitrary vector \( y \),

\[
y^T N y = y^T S^T \hat{N} S y = \hat{y}^T \hat{N} \hat{y} \geq 0.
\]

The matrix \( \tilde{K}^{-1}_{11} \) can be written in block matrix form as

\[
\tilde{K}^{-1}_{11} = \begin{bmatrix}
\tilde{B}^{-1}_{11} + \tilde{B}^{-1}_{12} \tilde{D}^{-1} \tilde{B}_{21} \tilde{B}^{-1}_{11} & -\tilde{B}^{-1}_{11} \tilde{B}_{12} \tilde{D}^{-1} \\
-\tilde{D}^{-1} \tilde{B}_{21} \tilde{B}^{-1}_{11} & \tilde{D}^{-1}
\end{bmatrix},
\]

with \( \tilde{D} = \tilde{B}_{22} - \tilde{B}_{21} \tilde{B}^{-1}_{11} \tilde{B}_{12} \). The choice \( \Delta = \delta I_3 \) (\( \delta \in \mathcal{R} \)) simplifies the algebra considerably and leads to

\[
\tilde{K}^T_{13} \tilde{K}^{-1}_{11} \tilde{K}^T_{13} = (1 - \delta)^2 \tilde{B}_{11}, \quad \text{and} \quad \tilde{K}^T_{23} \tilde{K}^{-1}_{11} \tilde{K}^T_{23} = \delta^2 \tilde{B}_{11}.
\]

That means that the last condition in (29) together with the assumption that \( \Sigma \) is symmetric leads to

\[
\Sigma \leq -\frac{[\beta(1-\delta)^2 + \alpha \delta^2] \varepsilon}{4 \alpha \beta} \tilde{B}_{11}.
\]  \( \text{(31)} \)

It is easy to verify that the right hand side of (31) has the least restrictive value \(-\varepsilon \tilde{B}_{11}/(4(\alpha + \beta))\) when \( \delta = \beta/(\alpha + \beta) \).

Now we have done all the necessary derivations and we can summarize the result in the following proposition.

**Proposition 5.1** If the conditions

\[
\begin{align*}
\Sigma^L_1 &\leq A^1_1/2, & \text{(inviscid stability)} \quad \text{(32a)} \\
\Sigma^L_1 &\leq -\varepsilon \tilde{B}_{11}/4(\alpha + \beta), & \text{(viscous stability)} \quad \text{(32b)} \\
\Sigma^L_2 &\leq -\varepsilon \beta I_1/(\alpha + \beta), & \text{(viscous stability)} \quad \text{(32c)} \\
\Sigma^R_1 &\leq \Sigma^L_1 - A_1, & \text{(inviscid conservation)} \quad \text{(32d)} \\
\Sigma^R_2 &\leq \Sigma^L_2 + \varepsilon I_1. & \text{(viscous conservation)} \quad \text{(32e)}
\end{align*}
\]

are satisfied, then the scheme (15)-(16) is stable and conservative.

**Remark** Recall that \( \alpha = \alpha^L p^L \) and \( \beta = \beta^R p^R \) (\( 0 \leq \alpha^L, \beta^R \leq 1 \)) where

\[
p^L = \Delta x^L : \begin{cases} 
\frac{1}{2} & \text{2nd order SBP} \\
\frac{17}{48} & \text{4th order SBP} \\
\frac{13649}{43200} & \text{6th order SBP}
\end{cases}
\]

\[
p^R = \Delta x^R : \begin{cases} 
\frac{1}{2} & \text{2nd order SBP} \\
\frac{17}{48} & \text{4th order SBP} \\
\frac{13649}{43200} & \text{6th order SBP}
\end{cases}
\]

In order to limit the spectral radius of the problem, the values of \( \alpha^L \) and \( \beta^R \) should be chosen as large as possible, that is \( \alpha^L = \beta^R = 1 \).
Remark Note again that the conservation conditions are a subset of the total number of stability conditions. The conditions (32) are sufficient (but might not be necessary and unique) for a stable and conservative interface treatment.

Remark The interface treatment do not introduce stiffness for the time integration procedure unless the penalty parameters in (32) are increased far beyond the necessary stability limit.

5.3 Practical implementation of the interface treatment

We now illustrate how to practically implement the method. Consider the interface between two sub-grids, as shown in figure 1. In the more standard multi-block interface treatment typically layers of unknowns are transferred between the sub-grids, see figure 2, and the boundaries can be treated in the same way as internal points. In case the grid over the interface is smooth (and the methodology is stable) this approach will give good results (even better than results obtained with the approach presented in this paper). However, in practice the grid over the interface will never be smooth (otherwise a splitting into sub-grids would not have been necessary) and will be clearly visible in the results. This is even true when a finite volume formulation is used instead of a finite difference method.

In contrast, the method presented in this work does not require the exchange of layers of unknowns; only data on the actual interface are required, see the RHS of equations (15a) and (15b). Consequently, the grid over the interface does not have to be smooth in order to obtain high quality numerical solutions. The method proceeds as follows, see also figure 3.
1 Compute for each of the sub-grids the spatial discretization as indicated by the LHS of equations (15a) and (15b). The requirements for this discretization are discussed in section 4.

2 The solution and the viscous flux vector of the vertices located at the interface are made available to the adjacent sub-grid.

3 The RHS of equations (15a) and (15b) can now be computed with the known values of the Σ’s, equation (32) and matrices $P^L_x$, $P^L_y$, $P^R_x$, and $P^R_y$. These terms are added to the spatial residual of the boundary nodes computed in item 1.

4 The entire spatial residual is known and a time integration step can be made.

Fig. 3. Interface treatment for the current method. Only data on the interface between the two sub-grids are exchanged. Note that the nodes on the interface are duplicated. One set belongs to the left sub-grid, the other set to the right sub-grid.

The entire procedure is repeated until the desired number of time steps is taken.

6 Numerical experiments

The derivation of the stability and conservation properties as expressed in Proposition 5.1 was done for the constant coefficient problem. We now verify that the result of the linear analysis is valid for the full non-linear Navier-Stokes equations.

6.1 Verification of accuracy and stability of the new interface treatment

We consider a calculation on two sub-domains coupled at an interface, see Figure 1. A stationary viscous shock problem where the middle of shock is located at the
interface is calculated. This problem has an analytical solution (for Prandtl number $Pr = 3/4$) which means that we have full control of the errors. The Mach number in front of the shock in the reference frame of the shock is 2.0 and the angle of the shock relative to the Cartesian frame is 15°. The Reynolds number $Re = 50.0$ is based on the Mach number of shock. The penalty terms in (32) are chosen by the minimum required values. We integrate the solution to steady-state using the third order low storage explicit time advancement scheme of Le and Moin [13].

In the hybrid scheme, the second derivative SBP operator is constructed with $2p$-th ($p = 1, 2, \ldots$) order accuracy internal and $(p - 1)$-th order at the boundary by using a diagonal norm. It was proved in [27] that if the solution is point wise bounded, the accuracy of the scheme is two orders higher than the accuracy of the second derivative approximation at the boundaries. The convergence rates for the second-, fourth-, sixth- and eighth- order schemes are thus 2, 3, 4 and 5, respectively. Since the errors for all variables (density, velocities and energy) are very similar, only the density errors are shown in our calculations. The accuracy is shown in Tables 1 and Table 2. The results are in agreement with the theory, see [8,9,27].

Table 2
The convergence rates of density on two non-uniform subdomains.

In the next calculation we consider the solution computed on the mesh in Figure 1. Figure 4(a) shows the density isolines using the 4th order discretization. The
Fig. 4. Density isolines for a 4th order calculation. 65×65 grid points are used in both sub domains.

corresponding cut at $y = 0$ can be found in Figure 4(b). The distribution of density close to the interface $x = 0$ is very smooth, which illustrates that the interface does not introduce large reflections and oscillations.

The density errors at $y = 0$ with SBP operators of different order are shown in Figures 5 and 6. Figure 5 shows the result for two uniform meshes, while in Figure 6 the right block is twice as coarse in the $x$-direction as the left block. Figures 5(a) and 6(a) show that the higher order schemes have rather large errors, comparable to the lower order schemes close to the interface $x = 0$ for the coarse mesh. However, when the mesh is refined, (129×129 and 65×129, respectively) the higher order schemes outperform the lower order schemes (see Figures 5(b) and 6(b)). Tables 1-2 and Figures 5-6 illustrate that the interface treatment is stable and accurate for all orders of accuracy.
Fig. 5. The errors in density at $y = 0$ with SBP operators of different orders.

Fig. 6. The errors in density at $y = 0$ with SBP operators of different orders.
(a) The density

(b) The error in density

Fig. 7. A 4th order calculation without the necessary viscous penalty terms.

To further illustrate the necessity of having correct penalty terms we neglect the viscous penalty term completely. This leads to a complete failure for all schemes (blow up in a couple of time steps), see Figure 7.

6.2 Two applications using the new interface treatment

We start by demonstrating the multi-block method on a moving shock problem. The unsteady computation has been carried out on a uniform grid of 65×65 in each block in combination with the the 4th order accurate SBP operator. All penalty parameters have the same values as for the previous steady case. The shock moves at Mach=0.15 under 45° degrees. Snapshots of the solution between $t = 0.0$ and $t = 8.0$ are shown in Figure 8. The shape of the shock through the interface $x = 0$
Density snapshots of the moving viscous shock problem

Fig. 8. Density isolines, 4th order accuracy for the unsteady shock problem.

remains intact, and the corresponding errors are small, see Figure 9.

To further illustrate the performance and applicability of the new interface treatment we consider the flow around a cylinder. The Mach number is 0.1 and the Reynolds number is 100. The computational results are shown for a large time ($T = 1500$) when the initial disturbances have died out and a periodic shedding of von Karman vortices has been established, see Figure 10. The flow field in terms of $\rho u$ is shown. The 5th order accurate method is used. We have used 5 blocks with $201 \times 101$ grid points in each block (the utmost right block is not included in the Figure). The global quantities such as Strouhal number, lift and drag are correctly predicted, for more details on this, see [28].

To investigate the specific topic of this paper we consider the solution close to the block interface on the upper “north east” side of the cylinder. Figure 11 shows the velocity field and the mesh. The mesh is clearly not smooth, but the solution is.

7 Conclusions

We have proved stability and conservation of a high order accurate multi-block finite difference method applied to the Navier-Stokes equations. As theoretical tools we have used difference operators of SBP type, a penalty technique for the interface conditions and the energy method.
Fig. 9. The error in density, 4th order accuracy for the unsteady shock problem.

Fig. 10. A global view of 5th order accurate cylinder calculation showing the shedding of von Karman vortices. The $x$-momentum $\rho u$ is shown.
Fig. 11. A zoom in on the velocity field and the mesh close to a block interface. The velocity field is continuous over the interface, the mesh is not.

The stability and conservation conditions are derived without approximations. This indicates that the derived conditions are sharp. That conclusion is supported by the numerical calculations which show that instabilities occur if the conditions are violated.

Mesh refinement studies for a steady viscous shock and computations of a moving viscous shock has been performed. We also considered the flow over a cylinder. The numerical experiments support the theoretical conclusions and show that the interface coupling is stable and converge at the correct order.
