ABSTRACT

Exergy is a concept that is gaining an increasingly wider recognition as a proper measure for the actual energy resources consumed, when energy is used. Energy as such is indestructible, but exergy is not. As entropy is generated while energy is used, exergy is consumed. Exergy can be interpreted as the qualitative content of energy, or as energy in its highest quality. Therefore, there is an interest in investigating this concept from as many theoretical aspects as possible.

In earlier papers the author has developed formulae for the exergy potential of a system of finitely extended objects, not necessarily having any environment. It was there shown that the classical formula for exergy obtains as one of the objects grows beyond all bounds thereby taking on the rôle as an environment.

In this current paper formulae are derived for the exergy content of an isolated body in thermodynamic disequilibrium, viewed as a system of infinitely many objects each with infinitesimal extension and in microscopic equilibrium.

Keywords: Exergy, available energy, availability, second law of thermodynamics, thermodynamic disequilibrium, microscopic reversibility, Gibbs, Onsager.

1: INTRODUCTION

The term exergy was coined in 1956 by Zoran Rant (1904-1972), (Rant, 1956). Earlier terms for this concept have been available energy and availability, inter alia (Kline, 1999). For a bibliography on exergy-related work, see (Wall, 1997). For arguments supporting the further development and application of this concept, please see e. g. (Rosen et al., 2008).

Exergy may be defined as the maximum amount of mechanical work that can be extracted from a source with given properties. The original concept relies on the existence of an environment that has constant intensive properties (temperature, pressure, chemical potentials, etc.), which are not affected by the processes taking place during the extraction. If a maximal amount of mechanical work is to be extracted, the processes involved need to be ideal in the sense that no entropy is generated, i. e. the processes are reversible.
The main development in this paper is based on the following universal principle (Grubbström, 1985):

*The exergy of a system of objects equals its total inner energy less the inner energy of a single body having the same total extensive properties as those of the system.*

The new basic results in this article are obtained from reinterpreting an object in disequilibrium as a system of infinitely many infinitesimal objects with heterogeneous intensive properties. These results are summarised in the single formula (21) in Section 4 below. By “thermodynamic disequilibrium” we thus mean that the object under consideration on a macroscopic level has a heterogeneous distribution of at least one intensive property (such as temperature or pressure). An object in equilibrium has all its intensive properties at constant levels throughout.

We summarise classical developments in Section 2, followed by formulae for the exergy of a set of finite objects in Section 3. Our new considerations are mainly developed in Section 4, in which a finite object in disequilibrium is interpreted as a continuous set of infinitely small objects, each in microscopic equilibrium, but with different intensive properties in the finite perspective. Section 5 offers three simple examples illustrating our findings, and a final section contains a summary and some ideas for further developments. The concept of microscopic equilibrium is elaborated in Section 4.

In our treatment, we make use of two abstract spaces, on the one hand the *thermodynamic configuration space* erected by one axis for each thermodynamic property considered, on the other, the *geometric space* in which the object is physically embedded, the latter space erected by axes representing spatial co-ordinates.

**2: THE INNER ENERGY FUNCTION AND CLASSICAL EXERGY EXPRESSION**

The following table lists the main notation used.
<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>

*Table 1. Basic notation.*

Additional notation will be introduced as the need arises.

The inner energy $U$ of a body (object, system, etc.) is often written in the following way

$$U = TS - pV + \mu N,$$

where $S$, $V$ and $N$ are the extensive properties *entropy*, *volume* and *mass* (molar content) respectively, and $T$, $p$ and $\mu$ the corresponding intensive properties *temperature*, *pressure* and *chemical potential*. This expression is easily generalised to an arbitrary number of extensive and corresponding intensive properties.

A homogeneous function $f(x_1, x_2, \ldots, x_n) = f(\mathbf{x})$ of order $l$, where $\mathbf{x}$ is a vector capturing its $n$ arguments, is defined as a function obeying

$$f(k\mathbf{x}) = k^l f(\mathbf{x}),$$

(2)
where \( k \) is any positive constant. A linearly homogeneous function is of unit order, \( l = 1 \). If \( y = \nabla f(x) = \left( \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2}, \ldots, \frac{\partial f}{\partial x_n} \right) \) is the gradient of such a function, we have:

\[
f(x) = \sum_{i=1}^{n} \frac{\partial f(x)}{\partial x_i} x_i = yx.
\]

(3)

Ever since the days of Josiah Willard Gibbs (1839-1903), (Gibbs, 1876, 1878), it has been recognised that the inner energy function is a linearly homogeneous function of the extensive properties of an object, that is with \( U(S, V, N) \), then the function obeys

\[
U(kS, kV, kN) = kU(S, V, N),
\]

(4)

for any positive constant \( k \).

Hence, the intensive properties \( T, p \) and \( \mu \), may be interpreted as together forming the gradient of the inner energy function in thermodynamic configuration space

\[
\nabla U(S, V, N) = \left( \frac{\partial U}{\partial S}, \frac{\partial U}{\partial V}, \frac{\partial U}{\partial N} \right) = (T, -p, \mu),
\]

(5)

and

\[
U(S, V, N) = (S, V, N)\nabla U(S, V, N) = (S, V, N)(T, -p, \mu) = TS - pV + \mu N,
\]

(6)

or in a more general form

\[
U(x) = x\nabla U(x) = xy.
\]

(7)

where \( x \) and \( y \) are vectors capturing extensive and intensive properties, respectively. Eq. (7) is a generalisation of Gibbs’ Fundamental Equation (Gibbs, 1876, 1878).

The classical formula given for the exergy content \( E \) of an object has the form (Ford, 1975, Eriksson et al., 1978, Wall, 1986):

\[
E = (T - T^*)S - (p - p^*)V + (\mu - \mu^*)N,
\]

(8)

where \( T, p, \) and \( \mu \) are the initial intensive properties of the source (object), \( T^*, p^* \) and \( \mu^* \) the constant intensive properties of the environment, and \( S, V, N \) the initial extensive properties of the source, or in a more general form

\[
E = x(\nabla U(x) - \nabla U(x^*)),
\]

(9)

where \( \nabla U(x^*) \) is a gradient vector holding the constant intensive properties of the environment.

As an example, we may consider an ideal gas, the inner energy of which most often is written
\[ U = cNT , \quad (10) \]

where \( c \) is the specific heat capacity (per mole and Kelvin at constant volume), and which obeys the ideal gas law:

\[ pV = NRT , \quad (11) \]

where \( R \) is the universal gas constant.

The standard formula (10) contains a mixture of intensive \((T)\) and extensive \((N)\) properties. But the inner energy may be written using only extensive properties (Grubbström, 1985, 2007)

\[ U = \text{const} \ e^{S/(cN)V^{-R/c}N^{1+R/c}} , \quad (12) \]

which is a linearly homogeneous function, where \( \text{const} \) is a positive undetermined constant. The gradient of \( U \) capturing its intensive properties is

\[ \nabla U = \text{const} \ e^{S/(cN)V^{-R/c}N^{1+R/c}} \left( \frac{1}{cN} - \frac{R}{cV} \left( 1 + \frac{R}{c} \right) \frac{1}{N} - \frac{S}{cN^2} \right) , \quad (13) \]

from which we identify:

\[ T = (\text{const} / c) e^{S/(cN)V^{-R/c}N^{1+R/c}} , \]
\[ \nabla U = -p = -(\text{const} R / c) e^{S/(cN)V^{-R/c-1}N^{1+R/c}} , \]
\[ \mu = (\text{const} / c) e^{S/(cN)V^{-R/c}N^{1+R/c}} (c + R - S / N) . \quad (14) \]

Making the simple multiplications \( pV = (\text{const} R / c) e^{S/(cN)V^{-R/c}N^{1+R/c}} \) and \( NRT = NR(\text{const} / c) e^{S/(cN)V^{-R/c}N^{1+R/c}} = (\text{const} R / c) e^{S/(cN)V^{-R/c}N^{1+R/c}} \), the ideal gas law obtains, and taking \( cNT = \text{const} e^{S/(cN)V^{-R/c}N^{1+R/c}} = U \), we have the standard inner energy formula (10). So the inner energy function (12) includes both of these relations.

**3: EXERGY FROM A SYSTEM OF FINITE OBJECTS**

Even if there is no environment, or if the environment is interpreted as an object with finite extension, the exergy concept may still be defined as the ideal maximum amount of mechanical work that a system of (at least two) objects may generate from the objects interacting (Grubbström, 1985, 2007).

The formula for the exergetic content of \( m \) bodies in the system may then be written:

\[ E = \sum_{i=1}^{m} U'(x') - \sum_{i=1}^{m} U'(x'') = \sum_{i=1}^{m} x' \nabla U(x') - \sum_{i=1}^{m} x'' \nabla U(x'') = \]
\[ = \sum_{i=1}^{m} x' \left( \nabla U(x') - \nabla U(x'') \right) , \quad (15) \]
where $U^i(x')$ is the inner energy of body $i$ having initial extensive properties $x'$, and $U^i(x''')$ the equilibrium inner energy of the same body when its extensive properties are $x'''$. Since the sum of extensive properties are conserved for reversible processes $m \sum_{i=1}^{m} x'^i = m \sum_{i=1}^{m} x'$, and the intensive properties the same for all objects in equilibrium $\nabla U(x''') = \nabla U(x''')$, $i, j = 1, 2, \ldots, m$, the right-hand member obtains.

At equilibrium, we have $\nabla U(x''') = \nabla U \left( \sum_{i=1}^{m} x'^i \right) = \nabla U \left( \sum_{i=1}^{m} x^i \right)$, for all $i$, so the exergy formula (15) may conveniently be written:

$$E = \sum_{i=1}^{m} x^i \left( \nabla U(x') - \nabla U \left( \sum_{i=1}^{m} x' \right) \right),$$

which contains only initial extensive properties as arguments.

It may be shown that the classical formula for exergy (8) results from making the extensive properties of one of the objects (the “environment”) grow beyond all bounds in its extensive properties. It may also be shown that the Second Law of Thermodynamics stating that total entropy does not decrease when allowing two objects to interact, is equivalent to requiring the inner energy function $U(x)$ to be weakly convex in its extensive arguments $x$, i.e. $d^2 U(x) \geq 0$, which is easily shown to hold for the function in Eq. (12) (Grubbström, 1985, 2007).

The first contribution to studying an exergetic system without any environment was probably made by Sergei Traustel (1903-1975) (Traustel, 1969).

4: EXERGY OF AN ISOLATED BODY IN DISEQUILIBRIUM

We now turn to our main purpose of this article, namely that of determining the exergetic content of an isolated body in disequilibrium. Such a body is interpreted as a system of infinitely many cells of zero extension. Using the same reasoning as by Norwegian-American Nobel Laureate Lars Onsager (1903-1976), (Onsager, 1931A, 1931B, Yourgrau et al., 1966), we may consider each of these arbitrarily small cells to be in thermodynamic equilibrium from a microscopic point of view (“microscopic reversibility”). This notion rests on a reasoning established by Onsager concerning the probability of a transition from one energy state to a second state being equal to the probability of a reverse transition (cf. also Tolman, 1938). Microscopic reversibility applies also when the object under consideration is in macroscopic disequilibrium. As a consequence, the present author applies this to the inner energy function for a body in equilibrium to be a valid description also for a sufficiently minute element of a body in thermodynamic disequilibrium. For a discussion of the term “microscopic reversibility” and the related term “detailed balance”, please also see Casimir (1945) and Morrissey (1975).
Let us first consider the inner energy function of a body in equilibrium \( U(\mathbf{x}) \). This function is linearly homogeneous. Defining the inner energy (volume) density as \( \rho_U = \frac{U(\mathbf{x})}{V} \), where \( V \) is one of the components belonging to \( \mathbf{x} \), this density becomes a homogeneous function of order zero:

\[
\rho_U(k\mathbf{x}) = U(k\mathbf{x}) / kV = kU(x) / kV = k^0 \rho_U(\mathbf{x}).
\]  

(17)

Let us further define the vector of densities by \( \mathbf{\rho} = \mathbf{x} / V \). Setting \( k=1/V \), ignoring temporarily that \( V \) is one of the variables, we obtain:

\[
\rho_U(\mathbf{x} / V) = \rho_U(\mathbf{\rho}) = U(\mathbf{\rho}) / kV = U(\mathbf{\rho}).
\]

(18)

Hence, the inner energy density for a body in equilibrium is the inner energy function with the extensive properties exchanged for their corresponding densities, the density of volume necessarily being unity \( \rho_v = 1 \).

For the special case of an ideal gas (remembering that \( \rho_v \equiv 1 \)), we may illustrate this by:

\[
\rho_U = U / V = \text{const} \ e^{\frac{E}{(c/\rho_0)} N - R c N + R c} = \text{const} \ e^{\frac{(S/V)(c/\rho_0)}{N / V} N + R c} = \\
= \text{const} \ e^{\rho_0 \cdot (c/\rho_0) \cdot \rho_N \cdot (1 + R / c)} = U(\rho_S, \rho_P, \rho_N).
\]

(19)

We introduce spatial co-ordinates contained in the vector \( \mathbf{\xi} = (\xi_1, \xi_2, \xi_3) \), and divide the body into small cells of size \( dV = d\xi_1 d\xi_2 d\xi_3 \). Each cell is located by its spatial co-ordinates \( \xi \) having the density vector \( \mathbf{\rho}(\xi) \) at \( \xi \) and assumed to be in microscopic equilibrium according to Onsager’s hypothesis (Onsager, 1931A, 1931B, Yourgrau et al., 1966, pp. 35 ff.). The initial total extensive properties are thus contained in the vector:

\[
\mathbf{x} = \iint_{\xi} \mathbf{\rho}(\xi) dV = \iiint_{\xi} \mathbf{\rho}(\xi) d\xi_1 d\xi_2 d\xi_3.
\]

(20)

Generalising (16), we thus obtain the exergy content \( E \) for the body according to:

\[
E = \iiint_{\xi} \rho_U(\mathbf{\rho}(\xi)) d\xi_1 d\xi_2 d\xi_3 - U \left( \iint_{\xi} \mathbf{\rho}(\xi) d\xi_1 d\xi_2 d\xi_3 \right) = \\
= \iiint_{\xi} U(\mathbf{\rho}(\xi)) d\xi_1 d\xi_2 d\xi_3 - U \left( \iint_{\xi} \mathbf{\rho}(\xi) d\xi_1 d\xi_2 d\xi_3 \right).
\]

(21)

That exergy is a non-negative entity is clear from \( U \) being a weakly convex function of its extensive arguments. A function \( U(\mathbf{z}) \), \( \mathbf{z} \) being a point in the space considered, is defined to be weakly convex if

\[
w_1 U(\mathbf{z}_1) + w_2 U(\mathbf{z}_2) \geq U(w_1 \mathbf{z}_1 + w_2 \mathbf{z}_2).
\]

(22)
where \( w_i \) and \( w_j \) are arbitrary non-negative weights adding up to unity. Letting \( z(\xi) \) be a vector-valued function of spatial co-ordinates \( \xi \), we then have \( w_i U(z(\xi_i)) + w_j U(z(\xi_j)) \geq U(w_i z(\xi_i) + w_j z(\xi_j)) \). The generalisation to a set of \( k \) points is obvious:

\[
\sum_{i=1}^{k} w_i U(z(\xi_i)) \geq U \left( \sum_{i=1}^{k} w_i z(\xi_i) \right),
\]

(23)

with \( \sum_{i=1}^{k} w_i = 1, \ w_i \geq 0 \). Let the points represent individual volume elements each of size \( dV \), \( w(\xi_i) dV = w_i \), \( w(\xi) \) being a non-negative function with \( \iiint w(\xi) d\xi_1 d\xi_2 d\xi_3 = 1 \). For a sufficiently large number \( k \) (small \( dV \)), the two members of (23) keeping their relation then approach:

\[
\iiint w(\xi) U(z(\xi)) d\xi_1 d\xi_2 d\xi_3 \geq U \left( \iiint w(\xi) z(\xi) d\xi_1 d\xi_2 d\xi_3 \right).
\]

(24)

With \( w(\xi) \) chosen as a constant function \( w(\xi) = 1/V \), and interpreting \( z(\xi) \) as \( \rho(\xi) \), we obtain

\[
\iiint \left( \rho(\xi) \right) d\xi_1 d\xi_2 d\xi_3 / V \geq U \left( \iiint \left( \rho(\xi) \right) d\xi_1 d\xi_2 d\xi_3 / V \right) = U \left( \iiint \left( \rho(\xi) \right) d\xi_1 d\xi_2 d\xi_3 / V \right),
\]

(25)

since \( U \) is linearly homogeneous. This ascertains that \( E \) in Eq. (21) is non-negative.

5: THREE ILLUSTRATIVE EXAMPLES

We now consider three simple interpretations illuminating the above general formulae for objects in thermodynamic disequilibrium, the first two assuming a one-dimensional “volume” and the third a case in 3D with thermodynamic properties varying along three spatial co-ordinates. A first case is when there is a constant temperature gradient in a solid body, a second when there is a constant pressure gradient in an enclosed ideal gas initially having the same temperature throughout, and the third when initial temperature may vary along one axis, pressure along a second axis, and molar density along a third axis.

**Solid body with constant temperature gradient**

The one-dimensional solid object is assumed to have a constant temperature gradient and a constant mass density \( \rho_N \). Let the temperature be written

\[
T(\xi) = T_L + \left(\xi / \hat{\xi}\right)(T_H - T_L),
\]

(26)

with the initial temperature being \( T_L \) at the low-temperature end where \( \xi = 0 \), and \( T_H \) at the high-temperature end where \( \xi = \hat{\xi} \), and where \( \hat{\xi} \) is the length (volume) of the object.
With $c$ denoting the heat capacity per unit of temperature and mole and using $\rho_N = \hat{N} / \xi$ with $\hat{N}$ denoting total mass, the initial inner energy of the body is

$$\int_{\xi=0}^{\xi} c\rho_N T d\xi = c\left(\hat{N} / \xi\right)\left(T_L + \left(\xi / \xi\right)(T_H - T_L)\right)d\xi = c\left(\hat{N} / \xi\right)\left(T_L\xi + \left(\xi / \xi\right)(T_H - T_L)\right) = c\hat{N}(T_L + T_H)/2,$$

i.e. the inner energy computed for the entire object using the average initial temperature $c\hat{N}(T_L + T_H)/2 = c\hat{N}T_{\text{average}}$.

For an object having only two extensive properties, entropy $S$ and mass $N$, the inner energy function is (Grubbström, 2007, Eq. 24, p. 710):

$$U(S, N) = \text{const} \ e^{\hat{S}/(cN)} N,$$

so:

$$T = \frac{\partial U}{\partial S} = \left(\text{const} / c\right) e^{\hat{S}/(cN)} = \left(\text{const} / c\right) e^{\hat{S}/(c\rho_N)} = \left(\text{const} / c\right) e^{\hat{S}/(c\hat{N})}.$$

The entropy density is therefore

$$\rho_s = \left(\hat{N} / \xi\right)\ln\left(cT(\xi)/\text{const}\right) = \left(\hat{N} / \xi\right)\ln\left(c\left(T_L + \left(\xi / \xi\right)(T_H - T_L)\right)/\text{const}\right),$$

and hence total initial entropy $\hat{S}$ (which is conserved)

$$\hat{S} = \int_{\xi=0}^{\xi} \rho_s(\xi) d\xi = \frac{\hat{N}}{\xi} \int_{\xi=0}^{\xi} \ln\left(cT(\xi)/\text{const}\right) d\xi = c\hat{N}\left(\ln\left(c\frac{T_L + \left(\xi / \xi\right)(T_H - T_L)}{\text{const}}\right) - 1\right) = c\hat{N}\left(\ln\left(c\frac{T_H}{T_L} - \frac{T_L}{T_H}\right)\right),$$

where $e$ is the base of the natural logarithm, and where the following primitive function has been used:

$$\int \ln(a + bz)\,dz = ((a / b) + z)\ln(a + bz) - z.$$

Total initial extensive properties are thus:
\[
\hat{x} = \int_{\xi} \hat{p}(\xi) d\xi = \left(\hat{S}, \xi, \hat{N}\right) = \left(c\hat{N} \ln \left(\frac{cT_L^{T_H/(T_H-T_L)}T_L^{-T_L/(T_H-T_L)}}{e \cdot \text{const}}\right), \xi, \hat{N}\right).
\]

The total equilibrium inner energy after maximal work extraction becomes

\[
U\left(\int_{\xi} \hat{p}(\xi) d\xi\right) = \text{const } e^{\hat{S}(\xi)} \hat{N} = c\hat{N}T_H^{T_H/(T_H-T_L)}T_L^{-T_L/(T_H-T_L)} / e,
\]

which shows that the equilibrium temperature \(T_{\text{final}}\) after maximal work extraction is:

\[
T_{\text{final}} = T_H^{T_H/(T_H-T_L)}T_L^{-T_L/(T_H-T_L)} / e.
\]

The initial inner energy density is obtained as

\[
\rho_v = U(\rho_S, \rho_N) = \text{const } e^{\rho_S(c\rho_N)} \rho_N = \text{const } e^{\rho_S(\xi)} \hat{N} / \xi,
\]

so, using (36), the initial total inner energy may be obtained alternatively from:

\[
\int_{\xi=0}^{\xi} \rho_v \left(p(\xi)\right) d\xi = \int_{\xi=0}^{\xi} \text{const } e^{\rho_S(\xi)} \rho_N d\xi = \int_{\xi=0}^{\xi} c \left(T_L + \left(\xi / \hat{\xi}\right)(T_H - T_L)\right) \left(\hat{N} / \hat{\xi}\right) d\xi =
\]

\[
eq c\hat{N} \left(T_H + T_L\right) / 2.
\]

Subtracting the equilibrium inner energy (after work extraction) from the initial inner energy finally provides us with an expression for the exergy content of the body:

\[
E = \int_{\xi=0}^{\xi} U\left(p(\xi)\right) d\xi - U\left(\int_{\xi=0}^{\xi} p(\xi) d\xi\right) = c\hat{N} \left(\frac{T_H + T_L}{2} - \frac{T_H^{T_H/(T_H-T_L)}T_L^{-T_L/(T_H-T_L)}}{e \cdot T_L^{T_H/(T_H-T_L)}}\right).
\]

We might compare this equation with the corresponding standard equation for a reversible heat engine using an amount of heat input \(Q\) at temperature \(T\) and producing work \(W\) with \(T^*\) being the ambient temperature:

\[
W = Q(1 - T^*/T),
\]

where \(1 - T^*/T\) is the “Carnot factor”. Interpreting \(c\hat{N} \left(T_H + T_L\right) / 2\) as heat \(Q\) and \(E\) as work \(W\), we find the “Carnot factor” expressed by:

\[
\text{Carnot factor} = \left(1 - \frac{2}{e} \frac{T_H^{T_H/(T_H-T_L)}T_L^{-T_L/(T_H-T_L)}}{T_L^{T_H/(T_H-T_L)}(T_H + T_L)}\right) = \left(1 - \frac{1}{T_{\text{final}}/T_{\text{average}}}\right).
\]
So, as expected, $T_{\text{final}}$ may be interpreted as the ambient temperature $T^*$, and $T_{\text{average}}$ as the input temperature.

If the two initial temperatures approach each other, the exergy of the body should approach zero, which is also shown by setting $t = T_L / (T_H - T_L)$ and taking

$$
\lim_{T_a \to T_t} T_{\text{final}} = \frac{1}{e^{T_H / (T_H - T_L)}} \frac{T_H}{T_L} = \frac{1}{e^{(1 + 1/t)(1 + (1/t)) T_L}} = \frac{1}{e^{(1 + 1/t)(1 + (1/t)) T_L}} = T_L,
$$

(41)

which makes $E$ in (38) zero and the “Carnot factor” zero.

Defining $\alpha$ from $T_H = (1 + \alpha) T_L$, i.e. $\alpha = 1/t$, where we accept that $\alpha$ might be negative, but greater than -1, we find that the “Carnot factor” may be written as $(1 - e^{\alpha(\alpha)})$, where $\alpha(\alpha) = \ln \left( \frac{2}{(1 + \alpha)^{(1/\alpha)} / (2 + \alpha)} / e \right)$. Analysing properties of $\alpha(\alpha)$ results in $\alpha(\alpha)$ always being negative, except for $\alpha = 0$, where $\alpha(0) = 0$, so the “Carnot factor” is positive and less than unity for $\alpha \neq 0$ and zero only for $\alpha = 0$ (the case of equal temperatures, $T_H = T_L$). Hence, we are assured that $T_{\text{final}} \leq T_{\text{average}}$, as intuition suggests. If any other conclusion, then $E \geq 0$ in Eq. (21) would have been violated.

If the initial entropy density $\rho S(\xi)$ instead would have been constant throughout the body, $\rho S(\xi) = \hat{\rho}_S$, for all $\xi$, then total initial entropy becomes

$$
\hat{S} = \int_{\xi=0}^{\xi} \rho S(\xi) d\xi = \hat{\rho}_S \xi,
$$

(42)

and total initial inner energy according to (36):

$$
\int_{\xi=0}^{\xi} \rho_U(\rho(\xi)) d\xi = \int_{\xi=0}^{\xi} \text{const } e^{\beta S(\xi) / (c\xi)} \left( \hat{N} / \xi \right) e^{\xi (c\xi) / (c\xi)} = \text{const } e^{\xi (c\xi) / (c\xi)} \xi.
$$

(43)

Temperature, according to (29), will take on the constant value $\hat{T}$

$$
T(\xi) = \frac{\partial U}{\partial S} = \left( \text{const } / c \right) e^{\beta S(\xi) / (c\xi)} = \left( \text{const } / c \right) e^{\beta S(\xi) / (c\xi)} = \left( \text{const } / c \right) e^{\xi (c\xi) / (c\xi)} = \hat{T},
$$

(44)

for all $\xi$. Equilibrium total inner energy will then remain at the level

$$
c \hat{N} \hat{T} = \text{const } \hat{N} e^{\xi (c\xi) / (c\xi)},
$$

(45)
and no mechanical work is possible to extract, i.e. $E = 0$.

As a final consideration, we examine the equilibrium state if no work would be extracted, i.e. the case when inner energy is conserved and intensive properties are equalised throughout the object. Conservation of inner energy implies $c \hat{N} T_{\text{average}} = c \hat{N} T^*$, where $T^*$ is the equilibrium temperature, which obviously must equal the initial average temperature. Furthermore, from Eq. (28), we obtain the equilibrium entropy $S^*$ as

$$S^* = c \hat{N} \ln \left( c T_{\text{average}} / \text{const} \right),$$

so using (31) the (maximal) increase in entropy becomes:

$$S^* - \hat{S} = c \hat{N} \ln \left( \frac{(T_H + T_L)/2}{T_H^{-T_0-\xi_T} / e} \right) = c \hat{N} \ln \left( T_{\text{average}} / T_{\text{final}} \right).$$

**Ideal gas with constant pressure gradient and constant temperature**

As a second illustration, we consider an ideal gas enclosed within a given one-dimensional volume with a constant pressure gradient, but having the same initial temperature throughout, say $T = \hat{T}$. Let the pressure be written

$$p(\xi) = \left( p_L + (\xi / \hat{\xi})(p_H - p_L) \right),$$

where, as before, $\xi$ is the one-dimensional spatial co-ordinate and $\hat{\xi}$ the spatial extension of the object (the gas), and where $p_H$ is the pressure at the high-pressure end, and $p_L$ at the low-pressure end.

For an ideal gas, the inner energy function may be written according to (12), which by (19) means that the inner energy density is distributed as:

$$\rho_u(\hat{\xi}) = U(\rho_S, \rho_V, \rho_u) = U\left( \rho_S(\hat{\xi}), 1, \rho_u(\hat{\xi}) \right) = \text{const } e^{\rho_S(\hat{\xi})/(c \rho_u(\hat{\xi}))} \rho_u(\hat{\xi})^{+R/c}.$$

But for an ideal gas in equilibrium we have $U = cNT$, so in microscopic equilibrium at the location $\hat{\xi}$ having the temperature $\hat{T}$ the inner energy density becomes

$$\rho_u(\hat{\xi}) = c \rho_u(\hat{\xi}) \hat{T},$$

so the initial total inner energy will be

$$U_{\text{initial}} = \int_{\hat{\xi} = 0}^{\hat{\xi}} \rho_u(\hat{\xi}) d\hat{\xi} = c \hat{T} \int_{\hat{\xi} = 0}^{\hat{\xi}} \rho_u(\hat{\xi}) d\hat{\xi} = c \hat{N} \hat{T}.$$

12
where \( \hat{N} \) is the initial mass (moles), a total extensive property which will be conserved.

Apart from \( \hat{\xi} \), there are the initial extensive properties entropy \( \hat{S} \) and mass \( \hat{N} \). Beginning with the latter, for an ideal gas with \( pV = NRT \), at the co-ordinate \( \hat{\xi} \) in microscopic equilibrium with \( T = \hat{T} \), we must have

\[
\rho_N(\hat{\xi}) = p(\hat{\xi}) / (RT),
\]

so

\[
\hat{N} = \int_{\xi=0}^{\xi} \rho_N(\xi) d\xi = \frac{1}{RT} \int_{\xi=0}^{\xi} p(\xi) d\xi = \frac{1}{RT} \int_{\xi=0}^{\xi} (p_L + (\hat{\xi} / \hat{\xi})(p_H - p_L)) d\xi = \hat{\xi} \left( \frac{p_H + p_L}{2RT} \right),
\]

which by (51) shows the initial average pressure \( p_{\text{average}} = (p_H + p_L) / 2 \) as an argument yielding the initial inner energy for the object as \( U_{\text{initial}} = (c / R) \hat{\xi} p_{\text{average}} \).

Concerning total initial entropy the computations are more lengthy. Taking the logarithm of (49) and (50), the entropy density is found to be

\[
\rho_S(\hat{\xi}) = c \rho_N(\hat{\xi}) \left( \ln \left( c \hat{T} / \text{const} \right) - \frac{R}{c} \ln \rho_N(\hat{\xi}) \right) =
\]

\[
= c \frac{p_L + (\hat{\xi} / \hat{\xi})(p_H - p_L)}{RT} \left( \ln \left( c \hat{T} / \text{const} \right) - \frac{R}{c} \ln \left( \frac{p_L + (\hat{\xi} / \hat{\xi})(p_H - p_L)}{RT} \right) \right).
\]

So total initial entropy \( \hat{S} \) (which is conserved) is

\[
\hat{S} = \int_{\xi=0}^{\xi} \rho_S(\xi) d\xi = \int_{\xi=0}^{\xi} \left( \frac{p_H + p_L}{2} \ln \left( e^{\xi/RT} \left( c \hat{T} / \text{const} \right)^{c/R} p_L^{p_L^2/(p_H^2 - p_L^2)} p_L^{p_L^2/(p_H^2 - p_L^2)} \right) \right) d\xi,
\]

where the following primitive function has been used:

\[
\int z \ln z dz = \frac{z^2}{2} (\ln z - 1 / 2).
\]

Total inner energy at equilibrium after maximal work extraction then becomes:

\[
U \left( \hat{\xi}, \hat{S}, \hat{N} \right) = \text{const} e^{\xi/(c \hat{T})} e^{-R/c} \hat{N}^{1+R/c} = \frac{c \hat{\xi} e^{R/(2c)}}{R} \left( p_L p_L^2 \left( p_H^2 - p_L^2 \right) \right)^{R/(c(p_H^2 - p_L^2))} p_{\text{average}}^{1+R/c},
\]

where, as before, \( p_{\text{average}} \) is initial average pressure.

According to (21), the exergy of this ideal gas in disequilibrium is therefore:
\[
E = \int_{\xi=0}^{\xi} \rho_U(\xi) d\xi - U(\hat{S}, \hat{\xi}, \hat{N}) = c\hat{N}\hat{T} - (c\hat{\xi} / R) e^{R/(2c)} \left( p_L p_H^2 p_H^{-p_L^2} \right) \frac{R}{c(p_H^{-p_L^2} - p_H^{p_L^2})} \left[ \frac{p_H + p_L}{2} \right]^{1+R/c} = \frac{c\hat{\xi}}{R} p_{\text{average}} \left[ 1 - e^{R/(2c)} \left( p_L p_H^2 p_H^{-p_L^2} \right) \left( p_H^{p_L^2} - p_H^{-p_L^2} \right) p_{\text{average}}^{R/c} \right].
\]

The final pressure after maximal work extraction will be:
\[
p_{\text{final}} = -\frac{\partial U(\hat{S}, \hat{\xi}, \hat{N})}{\partial \hat{\xi}} = (R / c) \text{const} e^{\hat{S}(c\hat{N})} e^{-1+R/c} \hat{N}^{1+R/c} = P_{\text{average}}^{1+R/c} \left( e^{1/2} \left( p_L p_H^2 p_H^{-p_L^2} \right) \frac{p_H^{p_L^2} - p_H^{-p_L^2}}{p_H^{-p_L^2} - p_H^{p_L^2}} \right)^{R/c},
\]
from which we find \( e^{1/2} \frac{p_L p_H^2 p_H^{-p_L^2}}{p_H^{p_L^2} - p_H^{-p_L^2}} = P_{\text{final}}^{c/R} P_{\text{average}}^{-1-c/R} \), so exergy may be written:
\[
E = (c / R) \hat{\xi} p_{\text{average}} \left( 1 - \frac{p_{\text{final}}}{p_{\text{average}}} \right).
\]

Again, we may interpret a "Carnot factor", in this case as:
\[
\text{Carnot factor} = \left( 1 - \frac{p_{\text{final}}}{p_{\text{average}}} \right).
\]

Since exergy is non-negative, we find \( p_{\text{final}} \leq p_{\text{average}} \) as expected. From the pressure being the same throughout the body after work extraction, the final temperature must obey \( p_{\text{final}} \hat{\xi} = \hat{N} T_{\text{final}} \), which, using (59), gives the final temperature \( T_{\text{final}} \):
\[
T_{\text{final}} = \frac{\hat{\xi}}{R N} P_{\text{average}}^{1+R/c} \left( e^{1/2} \left( p_L p_H^2 p_H^{-p_L^2} \right) \frac{p_H^{p_L^2} - p_H^{-p_L^2}}{p_H^{-p_L^2} - p_H^{p_L^2}} \right)^{R/c} = \hat{T} P_{\text{final}} / P_{\text{average}},
\]
which also shows the intuitive result \( T_{\text{final}} \leq \hat{T} \).

To complete this example, we examine the situation arising from a case when no work is extracted and the system is moved into equilibrium generating a maximal entropy increase. Then \( U_{\text{initial}} = U_{\text{final}} \), so \( c\hat{N}\hat{T} \) equals \( \text{const} e^{S^*(c\hat{N})} \hat{\xi}^{1+R/c} \hat{N}^{1+R/c} \), where \( S^* \) is final entropy. From (53), we thus obtain:
\[
S^* = c\hat{N} \ln \left( \frac{c\hat{\xi}^{1+R/c} P_{\text{average}}}{\text{const} R N^{1+R/c}} \right).
\]
Subtracting initial entropy \( \hat{S} \), using (55) and (59), yields the entropy increase as:
\[ S^* - \hat{S} = c \hat{N} \ln \left( \frac{P_{\text{average}}}{p_{\text{final}}} \right), \quad (64) \]

which may be compared with the similar expression in our first example (47).

If the two extreme pressures initially are equal, \( p_H = p_L \), one would expect the exergy content to be zero, which is also shown by using \( t = p_L / (p_H - p_L) \) and letting \( t \to \infty \):

\[
\lim_{p_H \to p_L} \frac{R(p_H)}{c(p_H)} \left( \frac{R(p_H)}{c(p_H)} \right) \left( p_H - p_L \right) = \frac{R(p_H)}{c(p_H)} = e^{R(2c) \left( t / (1 + t) \right)^2} = p_H \left( e^{R(2c) \left( t / (1 + t) \right)^2} \right) = \lim_{t \to \infty} \frac{e}{\left( 1 + 1/t \right)^{2t^2/(1 + 2t)}} = p_H. \quad (65)
\]

With this final pressure in (58), \( E \) becomes zero, quite as expected.

**Ideal gas with properties varying in three dimensions**

Keeping to an ideal gas, we choose as a third example a spatial three-dimensional case. Temperature may vary along a first \( \xi_1 \)-axis, pressure along a second \( \xi_2 \)-axis, and mass density along a third \( \xi_3 \)-axis. The spatial extension of the gas is \( \xi_1 \xi_2 \xi_3 \). Figure 1 offers an illustration. We investigate cases with given temperature, pressure and molar density gradients. Other cases with an entropy or chemical potential gradient might be of interest to examine, but are not equally accessible for analytical integration. By the ideal gas law (11), if two properties are specified, the third needs to follow suit, which limits the feasible number of cases.

![Figure 1. Basic conditions in third example.](image)

The following linear variations are alternatively assumed:
Along $\xi_1$-axis (temperature gradient)

$$T(\xi_1, \xi_2, \xi_3) = T_L + \left(\xi_1 / \xi_1\right)(T_H - T_L),$$  \hspace{1cm} (66)

along $\xi_2$-axis (pressure gradient)

$$p(\xi_1, \xi_2, \xi_3) = \left(p_L + \left(\xi_2 / \xi_2\right)(p_H - p_L)\right),$$  \hspace{1cm} (67)

along $\xi_3$-axis (molar density gradient)

$$\rho_N(\xi_1, \xi_2, \xi_3) = \rho_{NL} + \left(\xi_3 / \xi_3\right)(\rho_{NH} - \rho_{NL}),$$  \hspace{1cm} (68)

where subscripts with “$H$” refer to values at high property ends, and “$L$” at low property ends.

For an ideal gas we always have $\rho_N(\xi_1, \xi_2, \xi_3) = (c / R)p(\xi_1, \xi_2, \xi_3)$, so total initial inner energy in cases of a constant pressure gradient will then be:

$$U_{\text{initial}} = \iiint_{\xi_1, \xi_2, \xi_3} \rho_C(\xi_1, \xi_2, \xi_3) d\xi_1 d\xi_2 d\xi_3 = (c / R) \iiint_{\xi_1, \xi_2, \xi_3} \left(p_L + \xi_2 / \xi_2(p_H - p_L)\right) d\xi_1 d\xi_2 d\xi_3 =$$

$$= (c / R) \frac{p_L + p_H}{2} \xi_2 \xi_2 = (c / R) p_{\text{average}} \xi_2 \xi_2,$$  \hspace{1cm} (69)

where, as before, $p_{\text{average}} = (p_L + p_H) / 2$.

**Case I. Given constant temperature and pressure gradients**

As a first case we assume a temperature and pressure gradient (66) and (67). Starting by calculating the total molar content $\hat{N}$, from $c\rho_N T = (c / R)p$, we find the molar density to be

$$\rho_N(\xi_1, \xi_2, \xi_3) = \frac{\left(p_L + \xi_2 / \xi_2(p_H - p_L)\right)}{R\left(T_L + \xi_1 / \xi_1(T_H - T_L)\right)},$$  \hspace{1cm} (70)

which gives

$$\hat{N} = \iiint_{\xi_1, \xi_2, \xi_3} \frac{\left(p_L + \xi_2 / \xi_2(p_H - p_L)\right)}{R\left(T_L + \xi_1 / \xi_1(T_H - T_L)\right)} d\xi_1 d\xi_2 d\xi_3 = \xi_2 \xi_2 \iiint_{\xi_1, \xi_2, \xi_3} \left(p_L + \xi_2 / \xi_2(p_H - p_L)\right) d\xi_1 d\xi_2 d\xi_3 =$$

$$= \xi_2 \xi_2 \frac{p_H - p_L}{2} \int_{\xi_1 = 0}^{\xi_1} \frac{d\xi_1}{R\left(T_L + \xi_1 / \xi_1(T_H - T_L)\right)} = \frac{p_{\text{average}} \xi_2 \xi_2 \xi_2 \ln(T_H / T_L)}{R \xi_1 T_H - T_L}.$$  \hspace{1cm} (71)

Secondly, the entropy density $\rho_S$ is given by taking the logarithm of (19):
\[
\rho_s(\xi_1, \xi_2, \xi_3) = (c \rho_N)(\ln(c/(\text{const}R)) + \ln p - (1 + R/c) \ln \rho_N) = \frac{c p}{RT} \ln \left( \frac{c R^{R/c}}{\text{const} p^{-R/c} T^{1+(R/c)}} \right),
\]
where \( p \) and \( T \) have given distributions in space. So, after lengthy calculations, total initial entropy \( \dot{S} \) is obtained as:

\[
\dot{S} = \iiint_{\xi} c p(\xi_1) \ln \left( \frac{c R^{R/c}}{\text{const} p(\xi_2) T(\xi_3)^{(1+R/c)}} \right) d\xi_1 d\xi_2 d\xi_3 = \frac{c \xi_1 \xi_2 \xi_3}{R} \ln \left( \frac{T_H / T_L}{T_H - T_L} \right) p_{\text{average}} \ln \left( \frac{c \text{ const}}{R^{1/c} \sqrt{c (T_H / T_L)^{(1+R/c)}}} \left( \frac{p_H}{p_L} \frac{p_{H}^{2}}{p_{L}^{2} - p_{H}^{2}} \right)^{(1+R/c)} \right).
\]

Inserting \( \dot{S}, \dot{N} \) and \( V = \xi_1 \xi_2 \xi_3 \) into the inner energy function (12) gives us the inner energy after work extraction:

\[
U_{\text{final}} = (c / R) \sqrt{c} p_{\text{average}} \frac{\xi_1 \xi_2 \xi_3}{R} \left( \frac{T_H / T_L \ln (T_H / T_L)}{T_H - T_L} \right)^{(1+R/c)} \left( \frac{p_H}{p_L} \frac{p_{H}^{2}}{p_{L}^{2} - p_{H}^{2}} \right)^{(1+R/c)}.
\]

So, by subtracting \( U_{\text{final}} \) from \( U_{\text{initial}} \) in (69), exergy becomes

\[
E = (c / R) p_{\text{average}} \frac{\xi_1 \xi_2 \xi_3}{R} \left( 1 - \sqrt{c} \left( \frac{T_H / T_L \ln (T_H / T_L)}{T_H - T_L} \right)^{(1+R/c)} \frac{p_H}{p_L} \frac{p_{H}^{2}}{p_{L}^{2} - p_{H}^{2}} \right)^{(1+R/c)}.
\]

which also shows the corresponding “Carnot factor”.

Further final equilibrium properties \( T_{\text{final}} \) and \( p_{\text{final}} \) after work extraction are found from \( U_{\text{final}} = c \dot{N} T_{\text{final}} \) and \( p_{\text{final}} \frac{\xi_1 \xi_2 \xi_3}{R} = R \dot{N} T_{\text{final}} \):}

\[
T_{\text{final}} = \sqrt{c} \left( \frac{T_H / T_L}{T_H - T_L} \right)^{(1+R/c)} \left( \frac{\ln (T_H / T_L)}{T_H - T_L} \right)^{(1+R/c)} \left( \frac{p_H}{p_L} \frac{p_{H}^{2}}{p_{L}^{2} - p_{H}^{2}} \right)^{(1+R/c)}.
\]

\[
p_{\text{final}} = \sqrt{c} \left( \frac{T_H / T_L}{T_H - T_L} \right) p_{\text{average}} \left( \frac{\ln (T_H / T_L)}{T_H - T_L} \right)^{(1+R/c)} \left( \frac{p_H}{p_L} \frac{p_{H}^{2}}{p_{L}^{2} - p_{H}^{2}} \right)^{(1+R/c)}.
\]
Hence the “Carnot factor” may be written \((1 - p_{\text{final}} / p_{\text{average}})\) (which is the same as in (61)) and exergy becomes:

\[
E = (c / R) p_{\text{average}} \frac{\hat{p}}{s_{1}} \left(1 - p_{\text{final}} / p_{\text{average}}\right),
\]

which is the 3D equivalent of (60).

If instead of work extraction, the ideal gas had been brought to rest in equilibrium preserving its inner energy, we have \(U_{\text{initial}} = c\hat{N}T^*\) and \(p^* \frac{\hat{p}}{s_{1}} = \hat{N}RT^*\) with \(T^*\) and \(p^*\) being equilibrium temperature and pressure, which by (69) and (71) yields:

\[
T^* = (T_H - T_L) / \ln(T_H / T_L),
\]

\[
p^* = p_{\text{average}}.
\]

If \(T_H\) and \(T_L\) were equal, l’Hôpital’s rule applied to (79) shows \(T^* = T_L = T_H\), and if \(p_H\) and \(p_L\) were equal, then \(p^* = p_L = p_H\).

**Other cases**

Since the derivations of the other cases are very similar to Case I, we refrain from reporting details and conclude by listing results for all three cases in Tables 2-8. In the formulae, we use \(\hat{V} = \frac{\hat{p}}{s_{1}}\) for the fixed volume.

</tbody>
</table>

As a final consideration, we may assume an intermediate situation between the extremes of no work output (Table 8) and maximal work output (exergy), i.e. $W$, $0 < W < E$. Then, limiting ourselves to Case III, with $\Delta S$ being the entropy increase, we have

$$W = cT_{\text{average}} \rho_{\text{Nave}} \hat{V} \left(1 - e^{\Delta S/c(p_{\text{average}} \rho)} T_{\text{final}} / T_{\text{average}} \right),$$

showing the inverse relation between work output and entropy generation. With a zero entropy increase $\Delta S = 0$, then work output is exergy (cf. Table 7), and with no work output, the entropy increase is maximal (Table 8, first column). It should be noted that $T_{\text{final}}$ in (81) is the expression from Table 5 and not the final temperature if the work output were less than $E$.

Sensitivity analyses by examining effects from adjusting given parameters in (66)-(68) are easily performed, but left to the reader.

**CONCLUSIONS AND FURTHER RESEARCH**

After having summarised previous related findings in the first three sections of this paper, we derived general formulae for the exergetic content of an isolated object, which is in thermodynamic disequilibrium, meaning that the intensive properties of the body are distributed heterogeneously in space. This led to the basic formula (21) in Section 4. Our developments have
relied heavily on the validity of Gibbs’ *Fundamental Equation*, stating that the inner energy function is linearly homogeneous in its extensive variables, and on the notion of Onsager assuming that an infinitely small portion of an object may be considered to be in microscopic thermodynamic equilibrium.

Two one-dimensional examples and one three-dimensional example were provided in Section 5, on the one hand, a solid object with an initial constant temperature gradient, on the second, an ideal gas with a constant pressure gradient but having a homogeneous temperature distribution. In the third example, an ideal gas was considered with intensive properties varying along three axes. As side results from these examples, formulae have been provided for final state temperatures and pressures in the examples as well as comparisons with an alternative transition to equilibrium without work extraction.

Of course the results obtained are theoretical, and neither explain how the mechanical work is to be extracted nor what losses are expected. For instance, in the first example one could imagine a heat engine taking heat from a hot point and delivering it to a cold point, the difference in flows being the work output. But the hot and cold spots would probably all the time be moving in a complicated way. And one would also expect a simultaneous internal transfer of heat within the body due to conduction, necessarily destroying exergy. But exergy is the upper bound of work extracted, and although it is unattainable in practice, this measure still has a concrete physical meaning.

In future research there could be several avenues of approach opening themselves up for investigation. A first question might be to study a body in disequilibrium, when surrounded by an environment with constant intensive properties, and how the exergy formulae then are affected. But the real challenge would be met when combining disequilibrium exergetics with empirical laws like Fourier’s Law, Hartley-Fick’s Law, Ohm’s law, etc., by which the fluxes, at least as a first approximation, are proportional to corresponding thermodynamic gradients with densities of extensive properties as arguments. Then extreme generalisations of finite time thermodynamics of the Curzon-Ahlborn type (Curzon & Ahlborn, 1975) might not be far off to reach.
