Abstract. Previous theory for stimulated Brillouin scattering is reconsidered and generalized. We introduce an effective ion sound velocity that turns out to be useful in describing scattering instabilities.

1. Introduction

Brillouin scattering instabilities are well known in the context of laser fusion (e.g. Kruer 1973; Tsytoevich et al. 1973; Weiland and Wilhelmsson 1977; Rahman et al. 1981; Yadav et al. 2008; Simon 1995; Panwar and Sharma 2009). Mendonca (2012, review paper) has, in addition, examined such backscattering instabilities of electromagnetic beams carrying orbital angular momentum and stressed their relevance for plasma diagnostics.

In the 1970s it was predicted that the threshold values for stimulated Brillouin scattering can also be exceeded in ionospheric experiments (see the review papers Stenflo 2004; Gurevich 2007). The scattering by ion–cyclotron waves (e.g. Shukla and Tagare 1979; Samimi A. et al. 2013) and drift waves (Shukla et al. 1984) can then be important. Related experiments have later been outlined for piezoelectric semiconductor plasmas (e.g. Amin 2010).

In the present paper we are going to further extend the results of previous authors. Let us therefore start with the equation (Stenflo 1981; Shukla and Stenflo 2010)

\[
\frac{1}{\chi_s(\omega_0, \mathbf{k})} + \frac{1}{1 + \chi_i(\omega, \mathbf{k})} = \frac{k^2 |\mathbf{k}_\perp \times \mathbf{u}_0|^2}{k_z^2 D_\perp} + \frac{k^2 |\mathbf{k}_\perp \times \mathbf{u}_0|^2}{k^2 + D_\perp},
\]

(1.1)

where \(\chi_s(\omega, \mathbf{k})\) and \(\chi_i(\omega, \mathbf{k})\) are the standard low-frequency electron and ion susceptibilities for ion-acoustic and electrostatic ion–cyclotron waves, \(\omega_0\) and \(\mathbf{k}\) are the frequency and wave vector, \(\mathbf{k}_\perp = \mathbf{k} \pm \mathbf{k}_0\) is the wave vector of the upper and lower sideband, respectively, \(\mathbf{k}_0\) is the wave vector of the high frequency electromagnetic pump wave, \(\mathbf{u}_0 = e\mathbf{E}_0/m_e\omega_0\) is the electron quiver velocity of the pump with the electric field \(\mathbf{E}_0\) and the frequency \(\omega_0 = (k_0^2 \omega^2 + \omega_{pe}^2)^{1/2}\), \(-e\) is the electron charge, \(m_e\) is the electron mass, \(c\) is the speed of light in vacuum and \(\omega_{pe}\) is the electron plasma frequency. Furthermore, \(D_{\perp} = k_\perp^2 \omega^2 - \omega_{pe}^2\), \(\omega_{pe}\) in the absence of dissipation, where \(\omega_{pe} = \omega \pm \omega_0\). For \(\omega \ll \omega_0\) we have \(D_{\perp} \simeq \pm 2\omega_0(\omega - \delta_{\perp})\), where \(\delta_{\perp} = \mathbf{k} \cdot \mathbf{v}_g + k^2 c^2/2\omega_0\), and \(\mathbf{v}_g = \mathbf{k}_0 c^2/\omega_0\).

Introducing \(\varphi_{\perp}\) as the angle between \(\mathbf{k}_{\perp}\) and \(\mathbf{u}_0\), we note that (1.1) can be simplified to

\[
\left(\frac{1}{\chi_s(\omega_0, \mathbf{k})} + \frac{1}{1 + \chi_i(\omega, \mathbf{k})}\right) \left((\omega - \mathbf{k} \cdot \mathbf{v}_g)^2 - k^4 c^4/\omega_0^2\right)
\]

\[
= k^4 c^2 |\mathbf{u}_0|^2 \sin^2 \varphi/\omega_0^2
\]

(1.2)

provided \(\varphi_{\perp} \simeq \varphi_{\perp} = \varphi\), which, for example, holds for \(|\mathbf{k}| \ll |\mathbf{k}_0|, |\mathbf{k}_0| \ll |\mathbf{k}|\) or if the wave vectors are parallel. Equation (1.2) is in agreement with Drake et al. (1974, Eq. (44)) in the unmagnetized limit. They used this formula to deduce the growth rate for modulational instabilities. Furthermore, four-wave interaction has been studied in a magnetized plasma for a one-dimensional geometry (Stenflo 1978), generalized to include the effects of a very large pump amplitude, also allowing for \(|\mathbf{u}_0| > \omega_0/k_0\), which is not within the regime of validity of (1.2). The advantage with our formulas below is their applicability to a general three-dimensional geometry spanned by the wave vectors and the external magnetic field.

2. Derivations and results

Next we assume that the interaction with the lower sideband \((\omega_{\perp}, \mathbf{k}_{\perp})\) is dominant over the upper sideband \((\omega_{\perp}, \mathbf{k}_{\perp})\), i.e. \(|D_{\perp}| \ll |D_{\perp}|\). Rewriting (1.1) keeping only the interaction with the dominant sideband and assuming \(\omega \ll \Omega_e\) and \(\omega \gg kV_T\), where \(\Omega_e\) is the electron cyclotron frequency and \(V_T\) is the ion thermal velocity, we obtain (Shukla and Stenflo 2010)

\[
(\omega - \delta_{\perp}) \left(\omega^4 - \omega^2 \Omega_{IC}^2 + k_\perp^2 c_\perp^2 \Omega_{IC}^2\right)
\]

\[
= \left(\frac{\Omega_{IC}^2 k^2 - \omega^2 k^2}{2\omega_0}\right) \frac{|\mathbf{u}_0|^2 \sin^2 \varphi}{\omega_0^2}
\]

(2.1)

where \(\Omega_{IC}^2 = \Omega_e^2 + k^2 c_\perp^2\), \(\Omega_i\) is the ion–cyclotron frequency, \(c_\perp\) is the ion sound velocity, \(k = (k_\perp^2 + k_\parallel^2)^{1/2}\) and the subscripts \(\perp\) and \(\parallel\) respectively stand for components perpendicular and parallel to the external magnetic field \(\mathbf{B}_0 = B_0\mathbf{\hat{z}}\). Here \(\varphi\) is the angle between \(\mathbf{k}_{\perp}\) and \(\mathbf{u}_0\). Then we consider the parametric decay instability and thus
divide the frequency into its real and imaginary parts, that is \( \omega = \omega_r + i\gamma \). Furthermore, we take the sideband to be resonant, i.e.

\[
\omega - \delta_\omega = i\gamma
\]  

(2.2)
such that \( \omega_r = \delta_\omega \). Similarly, the low-frequency dispersion relation is supposed to be fulfilled, i.e.

\[
\omega^4 - \omega^2\Omega_{IC}^2 + k^2C_s^2\Omega_i^2 = 0,
\]  

(2.3)
in which case the growth rate is

\[
\gamma^2 = \frac{(\omega_r^2k^2 - \Omega_{IC}^2k_z^2)}{4(2\omega_r^2 - \omega^2\Omega_{IC}^2)} \frac{|\omega_0|^2 \omega_r^2 \sin^2 \varphi}{2C_s^2\omega_0},
\]  

(2.4)
where the right-hand side is a positive definite factor because of the condition (2.3). Next we are interested in finding the fastest growing decay products. For this purpose we introduce the azimuthal angle \( \phi \) for \( k \), i.e. we write \( k = k_\perp(\hat{x}\cos \phi + \hat{y}\sin \phi) + k_z\hat{z} \). If we let \( k_\parallel = k_0\hat{x} \), then the resonance condition for the sideband (2.2) is fulfilled for \( \cos \phi \simeq k^2/2k_0k_\perp \). With the azimuthal angle determined, we are free to vary \( k_z \) and \( k_\perp \) to maximize \( \gamma \). Writing

\[
\gamma^2 = I_{\pm}(k_z, k_\perp) \frac{|u_0|^2 \omega_r^2 \Omega_i \sin^2 \varphi}{2C_s^2\omega_0},
\]  

(2.5)
where \( I_{\pm} = (\omega_r^2k^2C_s^2 - \Omega_{IC}^2k_z^2C_s^2)/(4\omega_r^2 - \omega^2\Omega_{IC}^2) \) and here the index \( \pm \) refers to the two roots of (2.3) given by \( \omega_{\pm}^2 = (\Omega_{IC}^2/2) \pm \sqrt{(\Omega_{IC}^2/4) - k^2C_s^2\Omega_i^2} \), we thus want to find the maximum of \( I_{\pm}(k_z, k_\perp) \). In Figs. 1 and 2, \( I_+(k_z, k_\perp) \) and \( I_-(k_z, k_\perp) \) are shown as functions of the normalized wavenumbers \( k_zn = k_zC_s/\Omega_i \) and \( k_\perp n = k_\perp C_s/\Omega_i \). We see that the fastest growing modes occur for the negative root and for both \( k_zn \ll 1 \) and \( k_\perp n \ll 1 \) in which case \( I_- \) approaches 0.5 (Fig. 2). The other mode (Fig. 1) has \( I_+ \) always smaller than 0.2 and has a peak value for \( k_zn \ll 1 \) and \( k_\perp n \) slightly larger than unity. Thus, the parametric decay instability will mainly occur for the negative root and with parallel and perpendicular wavelengths much longer than the effective gyro radius \( C_s/\Omega_i \). Since the maximum occurs for small \( k \), it is always possible to fulfill the condition, \( \cos \phi \simeq k^2/2k_0k_\perp \) (for larger \( k \) this condition may lead to \( \cos \phi > 1 \), in which case the sideband resonance condition cannot be fulfilled simply by varying the azimuthal angle). Furthermore, for small \( k \) the factor \( \sin^2 \varphi \) in (2.5) is also maximized as we get \( \sin^2 \varphi \simeq 1 \).

For a strong pump wave \( u_0 \), the growth rate \( \gamma \) found in (2.4) may be comparable to \( \omega_r \). If \( \delta_- < \delta_+ \), we may still use (2.1), but naturally (2.2) and (2.3) cannot be applied for such a large pump amplitude. To study this case, we focus on the regime where \( \omega \ll \delta_- \), in which case (2.1) can be written as

\[
\omega^4 + (\Omega_i^2k_z^2 - \omega^2k^2) \left( C_s^2 + \frac{\sin^2 \varphi}{(2k \cdot k_0 - k^2)c^2} |u_0|^2 \omega_r^2 \right) - \omega^2\Omega_i^2 = 0.
\]  

(2.6)
Interestingly, this is exactly the same dispersion relation as the usual one (i.e. (2.3)) for the linear low-frequency mode, except that the ion-sound velocity is now substituted according to \( C_s^2 \rightarrow C_{\text{eff}}^2 \), where the effective ion-sound velocity is given by

\[
C_{\text{eff}}^2 = C_s^2 + \frac{\sin^2 \varphi}{(2k \cdot k_0 - k^2)c^2} |u_0|^2 \omega_r^2.
\]  

(2.7)
In order to get instabilities we must have \( C_{\text{eff}}^2 < 0 \) which in turn requires \( (2k \cdot k_0 - k^2) < 0 \), which is fulfilled for a broad set of parameters. The solutions can thus be written as

\[
\omega_{\pm}^2 = \frac{\Omega_{\text{eff}}^2}{2} \pm \sqrt{\frac{\Omega_{\text{eff}}^4}{4} - k^2C_{\text{eff}}^2\Omega_i^2},
\]  

(2.8)
where \( \Omega_{\text{eff}}^2 = \Omega_i^2 + k^2C_{\text{eff}}^2 \). While the cyclotron frequency may have a stabilizing influence for small \( k \), it is clear...
that when $C_{\text{eff}}^2$ turns negative, short wavelength modes of the negative root will have the factor $\Omega_i^2 + k^2 C_{\text{eff}}^2$ negative, in which case we always have an instability. The growth rate will then be of the order

$$\gamma \sim k \frac{|u_0| \omega_{\text{pi}}}{c |2k \cdot k_0 - k^2|^{1/2}}. \quad (2.9)$$

This expression for $\gamma$ can in principle be made very large since $2k \cdot k_0 - k^2$ can be adjusted to approach zero, but the validity of the expression breaks them down when $|2k \cdot k_0 - k^2|$ is of order $2|\omega_0|/c^2$. The maximum growth rate $\gamma_{\text{max}}$ is

$$\gamma_{\text{max}} \sim \left[ k^2 \frac{|u_0|^2 \omega_{\text{pi}}^2}{\omega_0} \right]^{1/3}. \quad (2.10)$$

However, we also require

$$\gamma_{\text{max}} \lesssim \frac{|u_0|^2 \omega_{\text{pi}}^2}{C_{\text{eff}}^2 \omega_0} \quad (2.11)$$

to keep $C_{\text{eff}}$ negative, which means that the maximum growth rate is limited by conditions (2.10) and (2.11). Since (2.10) can in principle be made arbitrarily large by increasing $k$, eventually the limit on the growth rate is guaranteed to be given by (2.11).

The transition from the parametric decay instability with a growth rate given by (2.5) to the large amplitude regime depends on the dimensionless amplitude $u_0 = |u_0| \omega_{\text{pi}} / C_s (\omega_0 \Omega_i)^{1/2}$. In the regime $u_0 < 1$, the growth rate scales as $\gamma / \Omega_i \sim u_0$, whereas for $u_0 > 1$, the scaling changes to $\gamma / \Omega_i \sim u_0^2$. The transition to a higher pump amplitude is accompanied by a shift in the wavelength of the low-frequency mode, i.e. from long to short wavelengths as compared to $C_s / \Omega_i$. For the large amplitude results to be valid, the amplitude must still be small enough for (1.1) to apply, which implies $|u_0| < \omega_0 / k_0$. If this condition is violated, the spectrum of the decay products will be more complicated than what we have considered here. In conclusion, there is thus a range of pump velocity amplitudes $C_s (\omega_0 \Omega_i)^{1/2} / \omega_{\text{pi}} < |u_0| < \omega_0 / k_0$ in which case the large amplitude scaling $\gamma / \Omega_i \sim u_0^2$ holds.

In order to compare with previous work, we finally consider the one-dimensional limit and then also include the contributions from both sidebands. The expression (2.7) accordingly turns out to be

$$C_{\text{eff}}^2 = C_s^2 - \frac{2 |u_0|^2 \omega_{\text{pi}}^2}{(k^2 - 4k_0^2) c^2}, \quad (2.12)$$

which is in agreement with the previous result (Stenflo 1978).

About 40 years ago, most space physicists could not imagine stimulated Brillouin scattering in the ionosphere. However, although very weak, this effect finally turned out to exist (see the review paper by Stenflo 2004). Recently, it was suggested (Sharma et al. 2011) that stimulated Brillouin scattering also may exist in biological tissues. According to the mobile telephone industry, this effect this time also is expected to be negligible. However, due to unexpected resonance phenomena we cannot be sure. More studies are thus necessary.
