Structured Abstract:

**Purpose:** We aimed to systematically review published empirical research on leadership as a determinant for the implementation of evidence-based practice (EBP) and to investigate leadership conceptualization and operationalization in this field.

**Design/methodology/approach:** A systematic review with narrative synthesis was conducted. Relevant bibliographic databases and reference lists of pertinent review articles were searched. To be included, a study had to involve empirical research and refer to both leadership and EBP in health care. Study quality was assessed with a structured instrument based on study design.

**Findings:** A total of 17 studies were included. Leadership was mostly viewed as a modifier for implementation success, acting through leadership support. Yet, there was definitional imprecision as well as conceptual inconsistency and studies seemed to inadequately address situational and contextual factors. Although referring to an organizational factor, the concept was mostly analysed at the individual or group level.

**Research limitations/implications:** The concept of leadership in implementation science seems to be not fully developed. It is unclear whether attempts to tap the concept of leadership in available instruments truly capture and measure the full range of the diverse leadership elements at various levels. Research in implementation science would benefit from a better integration of research findings from other disciplinary fields. Once a more mature concept has been established, researchers in implementation science could proceed to further elaborate operationalization and measurement.

**Originality/value**
Although the relevance of leadership in implementation science has been acknowledged, the conceptual base of leadership in this field has received only limited attention.

**Keywords**
Leadership, Conceptualization, Measurement, Evidence-based practice, Systematic review
Background

Despite widespread acceptance of the importance of implementing evidence-based practice (EBP) and the use of findings from scientific research in clinical practice, many patients still do not receive treatments with proven effectiveness or may receive care that is of little benefit or harmful (Dopson et al., 2002, Greenhalgh et al., 2004, Oxman et al., 1995). Implementation science has emerged as a vital interdisciplinary research field to address the challenges associated with the gap identified between the production and use of evidence in various settings. Explanations for this gap have largely focused on the characteristics of the individual provider, such as limited access to research, poor confidence in identifying and critically appraising evidence and perceived time restrictions to integrate research into clinical practice (Rycroft-Malone, 2008, Estabrooks et al., 2003, Squires et al., 2011).

However, within the field of implementation science, there has been increasing recognition of the role of the organizational context in the implementation of EBP (Durlak and DuPre, 2008, Greenhalgh et al., 2004, Fixsen et al., 2005). Leadership has been identified as an important contextual dimension (Taylor et al., 2011, Stetler et al., 2011, Newton et al., 2003); leadership commitment and active interest are behaviours that can positively affect the effectiveness of implementation (Helfrich et al., 2007). In addition, leaders’ influence on the subjective norms of potential adopters through interpersonal networks and communication must be considered (Leeman et al., 2007). Although there is no universally agreed definition of leadership, many conceptualizations reflect the assumption that leadership involves a process of exerting intentional influence by one person over another person or group in order to achieve a certain outcome in a group or organization (Gill, 2012, Yukl, 2006). There is evidence from outside the health care field of the influence of leadership on organizational culture, organizational performance (Ogbonna, 2000), organizational change (Battilana et al., 2010) and organizational innovation (Denti and Hemlin, 2012, Siegel and Kaemmerer, 1978).

Although the relevance of leadership in implementation science has been acknowledged, there seems to have been little empirical research on this concept in this field. Thus, the role of leadership in the implementation of EBP and the processes through which leaders can affect implementation success are largely unknown (Long et al., 2013, Rycroft-Malone et al., 2011, Wallin et al., 2006, Wong et al., 2013, Aarons et al., 2014). Therefore, the aim of this study was to systematically review published empirical research on leadership as a determinant for the implementation of EBP in health care and to investigate the conceptualization and operationalization of leadership in the field of implementation science.

Methods

Our approach is based on a conceptual scoping review (Levac et al., 2010) where we attempt to examine the range of research and to identify potential research gaps in the existing literature. The research question was formulated as follows: Based on an exploratory systematic review of empirical health care implementation studies on the concept of leadership, how is the leadership concept applied and contextualized? How do study authors define and specify the concept of leadership or its essential components and how is the construct measured?
The electronic databases PubMed and The Cochrane Library including the Cochrane Database of Systematic Reviews were searched and a separate search was conducted via the search function at the Implementation Science journal website (see Electronic Supplementary Material, Table S1 for search history). Medical Subject Headings as search terms when available were used or key words when appropriate. Search terms for leadership and research utilization or EBP were combined. All electronic searches were limited to “English language”, “German language” or “Swedish language” In addition, reference lists of pertinent review articles, key publications and commentaries were searched manually. All searches were conducted in October and November 2013. Due to limited resources, abstracts and full text articles could not be screened independently. Studies available in abstract form only were excluded. Eligibility criteria with respect to study design, publication type, study aim, setting, participants and outcomes were developed.

To be eligible for inclusion, a study had to explicitly refer to leadership as a construct (or leaders or leaders’ characteristics or leadership skills) in relation to the outcome of EBP or research use (research utilization, knowledge transfer, knowledge translation, knowledge utilization) in health care. Thus, studies exploring only general barriers or organizational factors affecting implementation outcomes were excluded. In addition, studies on instrument development or validation related to leadership and studies focusing only on conducting research (as opposed to research use or knowledge translation) were excluded. Studies exploring the effect of knowledge brokers, local opinion leaders, external facilitators, facilitation or change agents, as well as studies on leadership interventions (e.g. leadership development interventions, leadership training programs) were also excluded. No limitations with respect to a specific study design were applied.

One member of the research team (UR) was responsible for reading the abstracts of all the articles identified in this first search and applying the inclusion/exclusion criteria using an abstract screening tool. Inclusion/exclusion criteria were developed and discussed by all members of the research team (UR, SC, PN) and UR piloted the inclusion/exclusion criteria with a subset of abstracts retrieved from PubMed. Two members of the research team (SC and PN) reviewed the search terms, the search strategy, the abstract screening strategy, and the data abstraction criteria.

Data were abstracted from each included study by one member of the research team (UR) using predefined criteria (study aims, study design and methods; study participants; type of outcomes; health care setting and country where the study was conducted; main findings with respect to leadership: underlying theory, concept or framework; leadership construct; leadership operationalization and measurement; outcomes; type of data analysis; level of analysis, and stage of change process, i.e. pre-implementation, implementation, post-implementation).

Study quality or study reporting quality was assessed with a structured instrument based on the design of the individual study: Critical Appraisal Skills Program (CASP) for qualitative studies (Critical Appraisal Skills, 2013), the Assessment of Multiple Systematic Reviews (AMSTAR) tool for systematic reviews (Shea et al., 2007), and the Mixed Methods Appraisal Tool for mixed methods studies (Pluye et al., 2011). As there is currently no consensus guideline for survey research available, the data abstraction form in Bennett et al. (Bennett et al., 2010) was utilized. The operationalization of the concept was analysed based
on all studies using a survey approach and on qualitative studies providing published information on the respective interview guides.

Results

Our searches identified 1149 citations. We screened 144 full text articles for eligibility of which 17 were included in the study (Figure 1) (Aarons, 2006, Bergstrom et al., 2012, Boström et al., 2007, Brown and McCormack, 2011, Cummings et al., 2010, Damschroder et al., 2011, Estabrooks et al., 2007, Forsman et al., 2012, Gifford et al., 2007, Gifford et al., 2006, Hagedorn and Heideman, 2010, Ring et al., 2005, Sandstrom et al., 2011, Schultz and Kitson, 2010, Sharp et al., 2004, Stetler et al., 2009, Williams et al., 2011). Of these, two studies were assessed as high quality, nine were rated moderate quality, and five studies were of poor quality (methodological and/or reporting quality). The quality of a study using an action research approach could not be reliably determined with the available instruments.

Study characteristics

With regard to the professional groups involved, we found that 11 of the 17 studies (65%) referred to nursing; the remaining studies involved a variety of health professionals (physicians, clinical pharmacists, physical therapists, behavioural, nutritional, and mental health care practitioners). One of the studies was conducted by a multinational team in Uganda; the other studies were conducted in industrialized countries (Australia, Canada, Sweden, United Kingdom, United States). Seven of the 17 studies used a survey research approach, three were conducted with a mixed methods approach, five were qualitative studies, and two were (narrative) systematic reviews (Table 1 summarizes the main characteristics of the 17 studies included).

A clear classification of the outcome was possible for 15 of the 17 studies; six referred to implementation effectiveness (defined by a variety of measures, e.g. use of clinical guidelines, adoption, fidelity, or maintenance of a specific evidence-based program), seven referred to health professionals’ self-reported research use (or knowledge translation into practice, or attitudes towards research use, or attitudes towards adoption of EBPs), and two included both research use and implementation effectiveness.

Most of the study authors used an implementation model, conceptual framework or a theory for making assumptions on how determinants related to the outcome. In eight of the studies (Bergstrom et al., 2012, Boström et al., 2007, Brown and McCormack, 2011, Cummings et al., 2010, Estabrooks et al., 2007, Hagedorn and Heideman, 2010, Schultz and Kitson, 2010, Sharp et al., 2004), the authors referred to the Promoting Action on Research Implementation in Health Services (PARiHS) framework (Kitson et al., 1998). The PARiHS framework was used as an organizing or mapping tool in all of these studies, either for data structuring and selection of variables, as a heuristic for coding qualitative data, in instruments based on the framework, or in interview guide development.
**Conceptualization of leadership**

In all of the included 17 studies, leadership was understood as a modifier of implementation effectiveness or research use, where leaders’ positive influences and direct or indirect facilitative behaviours on implementation success were emphasized. Most studies explored leadership within a range of other contextual or organizational factors. In a few studies, the terms leadership, leader and management were used interchangeably (Boström et al., 2007, Damschroder et al., 2011, Forsman et al., 2012, Gifford et al., 2007, Sandstrom et al., 2011). Leadership was mostly conceptualized as leadership support (or management support). In nine of the 17 studies, the authors described leadership behaviours referring to the concept of transformational leadership (Table 2 gives an overview of the main findings).

**HERE (if possible): TABLE 2**

All studies referred to the importance of leadership, although they varied in the selection of specific dimensions from the whole range of leadership functions. Authors addressed both task-oriented leadership (goal emphasis, work facilitation, strategic thinking) and relations-oriented leadership (interaction facilitation, support, team building); the change-oriented leadership dimension (driving innovation, visionary thinking) was addressed less often. Nine of the 17 studies (Aarons, 2006, Bergstrom et al., 2012, Boström et al., 2007, Brown and McCormack, 2011, Cummings et al., 2010, Estabrooks et al., 2007, Hagedorn and Heideman, 2010, Schultz and Kitson, 2010, Stetler et al., 2009) addressed transformational leadership. Only one study addressed leadership in connection with specific or desirable attributes of a leader, distinguishing trainable skills from innate traits (Williams et al., 2011).

There was some variation with respect to the level of formal authority of leadership, yet all of the studies referred to some formally assigned hierarchical role. Only one study analysed leadership at the dyadic level of leader-follower (or supervisor-supervisee level), thus reflecting a close and supervisory relationship (Aarons, 2006). With a few exceptions, authors referred to the group or unit level as the formal authority for leadership, involving various titles (nurse manager, nursing manager, unit manager, ward manager, unit directors, administrators, clinical resource nurses, program manager) (Bergstrom et al., 2012, Boström et al., 2007, Brown and McCormack, 2011, Cummings et al., 2010, Damschroder et al., 2011, Gifford et al., 2007, Gifford et al., 2006, Ring et al., 2005, Sandstrom et al., 2011, Schultz and Kitson, 2010, Sharp et al., 2004). One study referred to both the dyadic and the organizational level (Estabrooks et al., 2007), and one to a range of upper and lower management levels (from unit nurse director to chief nurse) (Stetler et al., 2009). One of the few studies truly exploring leadership at the organizational level used the Organizational Readiness to Change Assessment instrument, where leadership was assessed at the senior leadership level in a respondent’s organization (Hagedorn and Heideman, 2010).

**Operationalization of leadership**

Nine of the 17 studies provided information that allowed assessment of how leadership was operationalized (Aarons, 2006, Boström et al., 2007, Brown and McCormack, 2011, Cummings et al., 2010, Estabrooks et al., 2007, Forsman et al., 2012, Hagedorn and Heideman, 2010, Schultz and Kitson, 2010, Stetler et al., 2009). The studies varied greatly with respect to how leadership was measured and how instruments were used.
Leadership as a supporting or hindering factor in direct relation to EBP was assessed in seven studies (Boström et al., 2007, Brown and McCormack, 2011, Cummings et al., 2010, Hagedorn and Heideman, 2010, Schultz and Kitson, 2010, Estabrooks et al., 2007, Forsman et al., 2012). However, validated instruments were used in only three of those studies: two studies (Cummings et al., 2010, Schultz and Kitson, 2010) used the Alberta Context Tool (ACT) (Estabrooks et al., 2009) and one study (Hagedorn and Heideman, 2010) used the Organizational Readiness to Change Assessment (ORCA) (Helfrich et al., 2009). In addition, two further studies (Aarons, 2006, Forsman et al., 2012) used instruments with a different approach in which leadership was addressed in relation to an outcome other than EBP; the authors then used data from this instrument in combination with an additional instrument developed to measure some aspect of EBP. In one of these two studies (Forsman et al., 2012), leadership dimensions were measured with the General Nordic Questionnaire for Psychological and Social Factors at Work (QPSNordic), a validated instrument to assess psychological, social, and organizational work conditions (Wannstrom et al., 2009). Data from this instrument were than related to information on the outcome, research use, measured by a non-validated instrument. Similarly, in the study by Aarons (Aarons, 2006), the Multifactor Leadership Questionnaire (Avolio et al., 1999), a validated scale of transformational leadership, was used to analyse the association with providers’ attitudes towards EBP.

Diverse leadership behaviours were tapped in the instruments administered; most of them addressed some form of support (at various levels), such as relations-oriented behaviours (i.e. solicits opinions; enhances collaboration; promotes team building; empowers, mentors and coaches; facilitates staff development), task-oriented behaviours (i.e. provides adequate staffing and resources; establishes project schedule and clarifies deliverables; sets clear goals and establishes role clarity; supervises and instructs), or, rarely, change-oriented behaviours (sets high priorities on success of innovation; is accessible, visible and available during implementation; describes clear strategic vision; appoints champions; rewards innovation and creativity, motivates change, sets high priority on successes). In three studies (Boström et al., 2007, Estabrooks et al., 2007, Gifford et al., 2007), leadership was analysed using only one or two (rather generically worded) items.

Discussion

This literature synthesis was undertaken to investigate how leadership has been conceptualized and operationalized in implementation science. We identified 17 studies that fulfilled the inclusion criteria. The nursing field dominated and all but one study were conducted in industrialized countries in a variety of health care settings. No experimental study was identified.

The authors of the 17 studies predominantly discussed leadership as a modifier or an intermediate factor for implementation success, yet the hypothesized mechanisms to affect outcomes were not specified and could not be tested with the study designs that were applied. Leadership was mostly used with a positive connotation; the studies addressed it as a potential supporting factor, rather than viewing lack of such support as a hindering factor.
Overall, the authors seemed to conceptualize leadership as supervisory or managerial leadership, thus not differentiating between the concepts of leadership and management. There has been some controversy in leadership theory whether leadership and management are essentially different concepts (Zaleznik, 2004) implicating mutually exclusive roles of leaders, but newer leadership theories argue for a more flexible model integrating both, albeit distinct, functions carried out by one person, depending on situational and contextual factors (Yukl and Lepsinger, 2005, Kotter, 1990). In the leadership literature, supervisory leadership refers to behaviours aiming to provide guidance, support and feedback in day-to-day situations at the work unit level; management, however, is understood as the function implementing leaders’ strategy but mainly deals with coordinative and administrative tasks (House and Aditya, 1997, Yukl, 1989). Thus, by not differentiating between managerial and leadership functions, the authors did not adequately address the situational and contextual factors relevant to understand the processes of how leadership might affect successful implementation. While managerial and leadership functions can complement each other and show some overlap, not adequately differentiating between these two distinct functions has research implications in that it obfuscates leadership’s conceptual base; moreover, it can have practical impacts when designing leadership development programs.

Many studies lacked a precise definition of the term leadership and there was conceptual inconsistency among the studies. The vagueness of conceptual definitions of leadership in the implementation science literature somewhat reflects the discourse within leadership research (Kempster and Parry, 2011). The concept of leadership is continually evolving, but leadership theories, specifically transformational and charismatic leadership theories, have been criticized for their conceptual and measurement weaknesses (Kelloway et al., 2000, Yukl, 1999a).

Nine of the 17 studies addressed transformational leadership, but the authors mostly referred to facilitative functions, such as general support, mentoring, or participative decision making. Hence, the authors’ conceptualizations reflected only a segment of leader behaviour described in transformational leadership theories (Avolio and Bass, 1988, Avolio et al., 1999, Podsakoff et al., 1996). According to transformational leadership theories, a transformational leader’s effect on followers’ motivation and performance can be explained by his or her attributes and behaviours (Avolio et al., 1999, Yukl, 1999b). In an idealized manner, the leader transforms and motivates followers through his or her idealized influence (or charisma), intellectual stimulation and individual consideration (Avolio and Bass, 1988). A transformational leader articulates a vision that is appealing and inspiring to followers, provides a role model for highly ethical behaviour, is able to raise follower awareness for transcendent collective interests, and helps followers achieve extraordinary goals (Avolio and Bass, 1988, Bass and Avolio, 1994). However, transformational leadership as used in the 17 implementation science studies referred to more mundane and practical functions. According to this conceptualization, transformational leader behaviours were described as communicating organizational values, clarifying roles, or showing personal support, and less on being visionary.

Although most of the study authors stressed the importance of leadership as an organizational factor, the concept was mostly analysed at the individual or group level; the authors did not address the larger organizational environment in which the unit was
embedded. Thus, there was a mismatch with respect to the level at which leadership was conceptualized and the level at which it was measured. Although it has been observed in organizational and management research that leadership operates differently at the individual, group and organizational levels (Day and Harrison, 2007), such complexity was not captured in the 17 studies. It has been stated elsewhere that factors influencing implementation success are thought to interact dynamically (Helfrich et al., 2010) and that effects of leadership on organizational outcomes can result from multiple levels of leadership simultaneously (O'Reilly et al., 2010), requiring coordination and collaboration between the different leadership levels and units (Yukl and Lepsinger, 2005). Furthermore, recent developments in leadership theory calling for an understanding of leadership more appropriate for collaborative contexts seem to reflect a move away from the traditional view on leadership “as commanding, telling, persuading, influencing, motivating - conceived as activities in which there is a point of origin (leaders) and a point of reception (followers)” (Drath 2008, p.651). In the same vein, collaborative leadership has been described as a new leadership style embedded in a collective leadership culture, including formal and informal leadership roles, requiring individual and collective leadership skills depending on situational and contextual circumstances (West et al., 2014).

Thus, to better understand a hypothesized supporting factor, authors should be more specific when describing context factors, potential dynamics and different types of leadership behaviour and relationships in future studies.

The maturity of a concept can be assessed critically in a qualitative process against a set of four criteria: clarity of definition; characteristics or attributes; preconditions and outcomes of the described concept; delineation of concept boundaries (Morse et al., 1996). Judged against these criteria, the concept of leadership in implementation science does not seem to have been fully developed, given the inconsistencies in its use, unclear definition, that its distinguishing features have not been fully identified and conceptual boundaries not clearly demarcated. It is unclear whether attempts to tap the concept of leadership in available instruments truly capture and measure the full range of the diverse elements of leadership at various levels relevant to implementation success.

Several of the studies included in this literature synthesis had obvious methodological deficiencies. Some of the survey instruments did not assess criterion and construct validity with respect to measuring leadership. Furthermore, data from instruments with sufficient psychometric properties to measure leadership were related to outcome data from an instrument lacking appropriate psychometric properties. Many instruments measuring the outcome (mostly research use) used self-reported measures without demonstrated validity. Not all of the mixed methods studies appropriately considered the relevance of this approach with respect to the research question or effectively integrated qualitative and quantitative data. Some of the qualitative data lacked a clear conceptual framework and used small samples selected only from a specific group, making it impossible to explore a full range of responses. One study was conducted as a secondary analysis of qualitative data not generated for the research questions addressed.

This literature synthesis has limitations that have to be acknowledged when interpreting the results. We did not conduct a comprehensive literature search. We restricted searches to primary research published in peer-reviewed journals in only two bibliographic
(although relevant and large) databases. Thus, we did not search grey literature and might have missed relevant but unpublished research. A further limitation of our work is that study selection and quality assessment were not done independently. Also, we did not define or specify specific outcomes of EBP a priori, so that potentially relevant studies could have been missed, also due to poor indexing of this concept in medical bibliographic databases.

**Conclusions**

Based on the 17 studies analysed, our narrative synthesis on leadership found that there is considerable variety in how leadership is addressed in current implementation science studies conducted in health care settings. Conceptualization of leadership in implementation science is characterized by imprecise definitions and inconsistent use of terms, thereby hindering a clear understanding of this concept’s role as a determinant of EBP and putting into question efforts of operationalization in this field. One example is the poor differentiation between management and leadership, a subject that needs further elaboration. The weak conceptual base has also practical implications affecting leadership development initiatives.

The findings of this study have a number of implications for future implementation science research. We identified conceptual gaps suggesting a need for theoretical advancement of the concept of leadership within implementation science. Because the concept of leadership does not seem to be sufficiently developed, differentiated and clearly positioned within the field of implementation science, it is unclear how useful its application in research and practice is at this point in time. Ongoing efforts to establish and refine terms and definitions as well as to promote consistent use of these terms and definitions of leadership within implementation science would benefit from a better integration of research findings from other disciplinary fields (e.g. organizational science). When a more mature concept has been established, researchers in implementation science could then proceed to further elaborate operationalization and measurement.
