The treatment of both cancer pain and non-cancer chronic pain is still suboptimal. Using the clinical practice of intrathecal analgesia as a starting point, the overall aim of this PhD thesis was to conduct pain research at the interface between clinical pain medicine and the growing field of human proteomics. Hence, the cerebrospinal fluid is at the centre of the present dissertation, both as a target for infusing analgesics and as a potential biological fluid for human biomarker studies. Will it be possible in the future for pain physicians to prescribe analgesics on the basis of precise information generated by a panel of biomarkers? The dissertation may perhaps been seen as a small step in that direction.
